xgboost

Release 2.1.1

xgboost developers

Aug 16, 2024
XGBoost is an optimized distributed gradient boosting library designed to be highly efficient, flexible and portable. It implements machine learning algorithms under the Gradient Boosting framework. XGBoost provides a parallel tree boosting (also known as GBDT, GBM) that solve many data science problems in a fast and accurate way. The same code runs on major distributed environment (Hadoop, SGE, MPI) and can solve problems beyond billions of examples.
1.1 Installation Guide

XGBoost provides binary packages for some language bindings. The binary packages support the GPU algorithm (device=cuda:0) on machines with NVIDIA GPUs. Please note that training with multiple GPUs is only supported for Linux platform. See XGBoost GPU Support. Also we have both stable releases and nightly builds, see below for how to install them. For building from source, visit this page.

1.1.1 Stable Release

Python

Pre-built binary wheels are uploaded to PyPI (Python Package Index) for each release. Supported platforms are Linux (x86_64, aarch64), Windows (x86_64) and MacOS (x86_64, Apple Silicon).

```
# Pip 21.3+ is required
pip install xgboost
```
You might need to run the command with \texttt{--user} flag or use \texttt{virtualenv} if you run into permission errors.

\textbf{Note}

Parts of the Python package now require glibc 2.28+

Starting from 2.1.0, XGBoost Python package will be distributed in two variants:

- \texttt{manylinux\_2\_28}: for recent Linux distros with glibc 2.28 or newer. This variant comes with all features enabled.
- \texttt{manylinux2014}: for old Linux distros with glibc older than 2.28. This variant does not support GPU algorithms or federated learning.

The \texttt{pip} package manager will automatically choose the correct variant depending on your system.

Starting from \textbf{May 31, 2025}, we will stop distributing the \texttt{manylinux2014} variant and exclusively distribute the \texttt{manylinux\_2\_28} variant. We made this decision so that our CI/CD pipeline won't have depend on software components that reached end-of-life (such as CentOS 7). We strongly encourage everyone to migrate to recent Linux distros in order to use future versions of XGBoost.

Note. If you want to use GPU algorithms or federated learning on an older Linux distro, you have two alternatives:

1. Upgrade to a recent Linux distro with glibc 2.28+. OR
2. Build XGBoost from the source.

\textbf{Note}

Windows users need to install Visual C++ Redistributable

XGBoost requires DLLs from \textbf{Visual C++ Redistributable} in order to function, so make sure to install it. Exception: If you have Visual Studio installed, you already have access to necessary libraries and thus don’t need to install Visual C++ Redistributable.

Capabilities of binary wheels for each platform:

<table>
<thead>
<tr>
<th>Platform</th>
<th>GPU</th>
<th>Multi-Node-Multi-GPU</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux x86_64</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Linux aarch64</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MacOS x86_64</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MacOS Apple Silicon</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Windows</td>
<td></td>
<td>✓</td>
</tr>
</tbody>
</table>

\textbf{Minimal installation (CPU-only)}

The default installation with \texttt{pip} will install the full XGBoost package, including the support for the GPU algorithms and federated learning.

You may choose to reduce the size of the installed package and save the disk space, by opting to install \texttt{xgboost-cpu} instead:

\texttt{pip install xgboost-cpu}
The \texttt{xgboost-cpu} variant will have drastically smaller disk footprint, but does not provide some features, such as the GPU algorithms and federated learning.

\textbf{Conda}

You may use the Conda packaging manager to install XGBoost:

\begin{verbatim}
conda install -c conda-forge py-xgboost
\end{verbatim}

Conda should be able to detect the existence of a GPU on your machine and install the correct variant of XGBoost. If you run into issues, try indicating the variant explicitly:

\begin{verbatim}
# CPU only
conda install -c conda-forge py-xgboost-cpu
# Use NVIDIA GPU
conda install -c conda-forge py-xgboost-gpu
\end{verbatim}

Visit the Miniconda website to obtain Conda.

\begin{note}
\texttt{py-xgboost-gpu} not available on Windows.

The \texttt{py-xgboost-gpu} is currently not available on Windows. If you are using Windows, please use \texttt{pip} to install XGBoost with GPU support.
\end{note}

\textbf{R}

- From CRAN:

\begin{verbatim}
install.packages("xgboost")
\end{verbatim}

\begin{note}
Using all CPU cores (threads) on Mac OSX

If you are using Mac OSX, you should first install OpenMP library (libomp) by running

\begin{verbatim}
brew install libomp
\end{verbatim}

and then run \texttt{install.packages("xgboost")}. Without OpenMP, XGBoost will only use a single CPU core, leading to suboptimal training speed.
\end{note}

- We also provide\textbf{ experimental} pre-built binary with GPU support. With this binary, you will be able to use the GPU algorithm without building XGBoost from the source. Download the binary package from the Releases page. The file name will be of the form \texttt{xgboost_r_gpu_[os]_[version].tar.gz}, where [os] is either \texttt{linux} or \texttt{win64}. (We build the binaries for 64-bit Linux and Windows.) Then install XGBoost by running:

\begin{verbatim}
# Install dependencies
R -q -e "install.packages(c('data.table', 'jsonlite'))"
# Install XGBoost
R CMD INSTALL ./xgboost_r_gpu_linux.tar.gz
\end{verbatim}
JVM

- XGBoost4j/XGBoost4j-Spark

Listing 1: Maven

```xml
<properties>
  ...
  <!-- Specify Scala version in package name -->
  <scala.binary.version>2.12</scala.binary.version>
</properties>

<dependencies>
  ...
  <dependency>
    <groupId>ml.dmlc</groupId>
    <artifactId>xgboost4j_${scala.binary.version}</artifactId>
    <version>latest_version_num</version>
  </dependency>
  <dependency>
    <groupId>ml.dmlc</groupId>
    <artifactId>xgboost4j-spark_${scala.binary.version}</artifactId>
    <version>latest_version_num</version>
  </dependency>
</dependencies>
```

Listing 2: sbt

```scala
libraryDependencies ++= Seq(
  "ml.dmlc" %% "xgboost4j" % "latest_version_num",
  "ml.dmlc" %% "xgboost4j-spark" % "latest_version_num"
)
```

- XGBoost4j-GPU/XGBoost4j-Spark-GPU

Listing 3: Maven

```xml
<properties>
  ...
  <!-- Specify Scala version in package name -->
  <scala.binary.version>2.12</scala.binary.version>
</properties>

<dependencies>
  ...
  <dependency>
    <groupId>ml.dmlc</groupId>
    <artifactId>xgboost4j-gpu_${scala.binary.version}</artifactId>
    <version>latest_version_num</version>
  </dependency>
  <dependency>
    <groupId>ml.dmlc</groupId>
    <artifactId>xgboost4j-spark-gpu_${scala.binary.version}</artifactId>
    <version>latest_version_num</version>
  </dependency>
</dependencies>
```
Listing 4: sbt

```scala
libraryDependencies ++= Seq(
  "ml.dmlc" %% "xgboost4j-gpu" % "latest_version_num",
  "ml.dmlc" %% "xgboost4j-spark-gpu" % "latest_version_num"
)
```

This will check out the latest stable version from the Maven Central.

For the latest release version number, please check release page.

To enable the GPU algorithm (device='cuda'), use artifacts `xgboost4j-gpu_2.12` and `xgboost4j-spark-gpu_2.12` instead (note the gpu suffix).

**Note**

Windows not supported in the JVM package

Currently, XGBoost4J-Spark does not support Windows platform, as the distributed training algorithm is inoperational for Windows. Please use Linux or MacOS.

### 1.1.2 Nightly Build

**Python**

Nightly builds are available. You can go to this page, find the wheel with the commit ID you want and install it with pip:

```
pip install <url to the wheel>
```

The capability of Python pre-built wheel is the same as stable release.

**R**

Other than standard CRAN installation, we also provide experimental pre-built binary on with GPU support. You can go to this page, Find the commit ID you want to install and then locate the file `xgboost_r_gpu_[os]_[commit].tar.gz`, where `[os]` is either linux or win64. (We build the binaries for 64-bit Linux and Windows.) Download it and run the following commands:

```
# Install dependencies
R -q -e "install.packages(c('data.table', 'jsonlite', 'remotes'))"
# Install XGBoost
R CMD INSTALL ./xgboost_r_gpu_linux.tar.gz
```
JVM

- XGBoost4j/XGBoost4j-Spark

Listing 5: Maven

```
<repository>
  <id>XGBoost4J Snapshot Repo</id>
  <name>XGBoost4J Snapshot Repo</name>
  <url>https://s3-us-west-2.amazonaws.com/xgboost-maven-repo/snapshot/</url>
</repository>
```

Listing 6: sbt

```
resolvers += "XGBoost4J Snapshot Repo" at "https://s3-us-west-2.amazonaws.com/xgboost-maven-repo/snapshot/"
```

Then add XGBoost4J as a dependency:

Listing 7: maven

```
<properties>
  ...
  <!-- Specify Scala version in package name -->
  <scala.binary.version>2.12</scala.binary.version>
</properties>

<dependencies>
  ...
  <dependency>
    <groupId>ml.dmlc</groupId>
    <artifactId>xgboost4j_${scala.binary.version}</artifactId>
    <version>latest_version_num-SNAPSHOT</version>
  </dependency>
  <dependency>
    <groupId>ml.dmlc</groupId>
    <artifactId>xgboost4j-spark_${scala.binary.version}</artifactId>
    <version>latest_version_num-SNAPSHOT</version>
  </dependency>
</dependencies>
```

Listing 8: sbt

```
libraryDependencies ++= Seq(
  "ml.dmlc" %% "xgboost4j" % "latest_version_num-SNAPSHOT",
  "ml.dmlc" %% "xgboost4j-spark" % "latest_version_num-SNAPSHOT"
)
```

- XGBoost4j-GPU/XGBoost4j-Spark-GPU

Listing 9: maven

```
<properties>
  ...
```

(continues on next page)
<dependency>
  <groupId>ml.dmlc</groupId>
  <artifactId>xgboost4j-gpu_${scala.binary.version}</artifactId>
  <version>latest_version_num-SNAPSHOT</version>
</dependency>

<dependency>
  <groupId>ml.dmlc</groupId>
  <artifactId>xgboost4j-spark-gpu_${scala.binary.version}</artifactId>
  <version>latest_version_num-SNAPSHOT</version>
</dependency>

Listing 10: sbt

libraryDependencies += Seq(
  "ml.dmlc" %% "xgboost4j-gpu" % "latest_version_num-SNAPSHOT",
  "ml.dmlc" %% "xgboost4j-spark-gpu" % "latest_version_num-SNAPSHOT"
)

Look up the version field in pom.xml to get the correct version number.

The SNAPSHOT JARs are hosted by the XGBoost project. Every commit in the master branch will automatically trigger generation of a new SNAPSHOT JAR. You can control how often Maven should upgrade your SNAPSHOT installation by specifying updatePolicy. See here for details.

You can browse the file listing of the Maven repository at https://s3-us-west-2.amazonaws.com/xgboost-maven-repo/list.html.

To enable the GPU algorithm (device='cuda'), use artifacts xgboost4j-gpu_2.12 and xgboost4j-spark-gpu_2.12 instead (note the gpu suffix).

1.2 Building From Source

This page gives instructions on how to build and install XGBoost from the source code on various systems. If the instructions do not work for you, please feel free to ask questions at the user forum.

Note

Pre-built binary is available: now with GPU support

Consider installing XGBoost from a pre-built binary, to avoid the trouble of building XGBoost from the source. Checkout Installation Guide.
1.2.1 Obtaining the Source Code

To obtain the development repository of XGBoost, one needs to use `git`.

**Note**

Use of Git submodules

XGBoost uses Git submodules to manage dependencies. So when you clone the repo, remember to specify `--recursive` option:

```
git clone --recursive https://github.com/dmlc/xgboost
```

For windows users who use github tools, you can open the git shell and type the following command:

```
git submodule init
git submodule update
```
1.2.2 Building the Shared Library

This section describes the procedure to build the shared library and CLI interface independently. For building language specific package, see corresponding sections in this document.

- On Linux and other UNIX-like systems, the target library is libxgboost.so
- On MacOS, the target library is libxgboost.dylib
- On Windows the target library is xgboost.dll

This shared library is used by different language bindings (with some additions depending on the binding you choose). The minimal building requirement is

- A recent C++ compiler supporting C++11 (g++-5.0 or higher)
- CMake 3.14 or higher.

For a list of CMake options like GPU support, see #-- options in CMakeLists.txt on top level of source tree.

Building on Linux and other UNIX-like systems

After obtaining the source code, one builds XGBoost by running CMake:

```
cd xgboost
mkdir build
cd build
cmake ..
make -j$(nproc)
```

Building on MacOS

Obtain libomp from Homebrew:

```
brew install libomp
```

Rest is the same as building on Linux.

Building on Windows

XGBoost support compilation with Microsoft Visual Studio and MinGW. To build with Visual Studio, we will need CMake. Make sure to install a recent version of CMake. Then run the following from the root of the XGBoost directory:

```
mkdir build
cd build
cmake .. -G"Visual Studio 14 2015 Win64"
# for VS15: cmake .. -G"Visual Studio 15 2017" -A x64
# for VS16: cmake .. -G"Visual Studio 16 2019" -A x64
cmake --build . --config Release
```

This specifies an out of source build using the Visual Studio 64 bit generator. (Change the -G option appropriately if you have a different version of Visual Studio installed.)

After the build process successfully ends, you will find a xgboost.dll library file inside ./lib/ folder. Some notes on using MinGW is added in Building Python Package for Windows with MinGW-w64 (Advanced).
## Building with GPU support

XGBoost can be built with GPU support for both Linux and Windows using CMake. See *Building R package with GPU support* for special instructions for R.

An up-to-date version of the CUDA toolkit is required.

### Note

Checking your compiler version

CUDA is really picky about supported compilers, a table for the compatible compilers for the latest CUDA version on Linux can be seen [here](https://docs.nvidia.com/cuda/index.html).

Some distros package a compatible gcc version with CUDA. If you run into compiler errors with `nvcc`, try specifying the correct compiler with `-DCMAKE_CXX_COMPILER=/path/to/correct/g++ -DCMAKE_C_COMPILER=/path/to/correct/gcc`. On Arch Linux, for example, both binaries can be found under `/opt/cuda/bin/`.

From the command line on Linux starting from the XGBoost directory:
```
mkdir build
cd build
cmake .. -DUSE_CUDA=ON
make -j4
```

### Note

Specifying compute capability

To speed up compilation, the compute version specific to your GPU could be passed to cmake as, e.g., `-DCMAKE_CUDA_ARCHITECTURES=75`. A quick explanation and numbers for some architectures can be found in [this page](https://docs.nvidia.com/cuda/index.html).

### Note

Faster distributed GPU training with NCCL

By default, distributed GPU training is enabled with the option `USE_NCCL=ON`. Distributed GPU training depends on NCCL2, available at [this link](https://developer.nvidia.com/nccl). Since NCCL2 is only available for Linux machines, **Distributed GPU training is available only for Linux**.

```
mkdir build
cd build
cmake .. -DUSE_CUDA=ON -DUSE_NCCL=ON -DNVCC_ROOT=/path/to/nccl2
make -j4
```

Some additional flags are available for NCCL, `BUILD_WITH_SHARED_NCCL` enables building XGBoost with NCCL as a shared library, while `USE_DLOPEN_NCCL` enables XGBoost to load NCCL at runtime using `dlopen`.

On Windows, run CMake as follows:
mkdir build
cd build
cmake .. -G"Visual Studio 17 2022" -A x64 -DUSE_CUDA=ON

(Change the -G option appropriately if you have a different version of Visual Studio installed.)

The above cmake configuration run will create an xgboost.sln solution file in the build directory. Build this solution in Release mode, either from Visual studio or from command line:

cmake --build . --target xgboost --config Release

To speed up compilation, run multiple jobs in parallel by appending option -- /MP.

Federated Learning

The federated learning plugin requires grpc and protobuf. To install grpc, refer to the installation guide from the gRPC website. Alternatively, one can use the libgrpc and the protobuf package from conda forge if conda is available. After obtaining the required dependencies, enable the flag: -DPLUGIN_FEDERATED=ON when running CMake. Please note that only Linux is supported for the federated plugin.

1.2.3 Building Python Package from Source

The Python package is located at python-package/.

Building Python Package with Default Toolchains

There are several ways to build and install the package from source:

1. Build C++ core with CMake first

   You can first build C++ library using CMake as described in Building the Shared Library. After compilation, a shared library will appear in lib/ directory. On Linux distributions, the shared library is lib/libxgboost.so. The install script pip install . will reuse the shared library instead of compiling it from scratch, making it quite fast to run.

   $ cd python-package/
   $ pip install .  # Will re-use lib/libxgboost.so

2. Install the Python package directly

   You can navigate to python-package/ directory and install the Python package directly by running

   $ cd python-package/
   $ pip install -v .

   which will compile XGBoost's native (C++) code using default CMake flags. To enable additional compilation options, pass corresponding --config-settings:

   $ pip install -v . --config-settings use_cuda=True --config-settings use_nccl=True

   Use Pip 22.1 or later to use --config-settings option.

   Here are the available options for --config-settings:
```python
@dataclasses.dataclass
class BuildConfiguration:  # pylint: disable=R0902
    '''Configurations use when building libxgboost'''

    # Whether to hide C++ symbols in libxgboost.so
    hide_cxx_symbols: bool = True
    # Whether to enable OpenMP
    use_openmp: bool = True
    # Whether to enable CUDA
    use_cuda: bool = False
    # Whether to enable NCCL
    use_nccl: bool = False
    # Whether to load nccl dynamically
    use_dlopen_nccl: bool = False
    # Whether to enable federated learning
    plugin_federated: bool = False
    # Whether to enable rmm support
    plugin_rmm: bool = False
    # Special option: See explanation below
    use_system_libxgboost: bool = False
```

use_system_libxgboost is a special option. See Item 4 below for detailed description.

1. **Note**

Verbose flag recommended

As `pip install .` will build C++ code, it will take a while to complete. To ensure that the build is progressing successfully, we suggest that you add the verbose flag (`-v`) when invoking `pip install`.

3. **Editable installation**

To further enable rapid development and iteration, we provide an **editable installation**. In an editable installation, the installed package is simply a symbolic link to your working copy of the XGBoost source code. So every changes you make to your source directory will be immediately visible to the Python interpreter. To install XGBoost as editable installation, first build the shared library as previously described, then install the Python package:

```
# Under xgboost source directory
mkdir build
cd build
# Build shared library libxgboost.so
make .. -GNinja
ninja
# Install as editable installation
cd ../python-package
pip install -e .
```

4. **Use libxgboost.so on system path.**

This option is useful for package managers that wish to separately package libxgboost.so and the XGBoost Python package. For example, Conda publishes libxgboost (for the shared library) and py-xgboost (for the Python package).
To use this option, first make sure that `libxgboost.so` exists in the system library path:

```python
import sys
import pathlib
libpath = pathlib.Path(sys.base_prefix).joinpath("lib", "libxgboost.so")
assert libpath.exists()
```

Then pass `use_system_libxgboost=True` option to `pip install`:

```bash
cd python-package
pip install --config-settings use_system_libxgboost=True
```

---

**Note**

See [Notes on packaging XGBoost’s Python package](#) for instructions on packaging and distributing XGBoost as Python distributions.

### Building Python Package for Windows with MinGW-w64 (Advanced)

Windows versions of Python are built with Microsoft Visual Studio. Usually Python binary modules are built with the same compiler the interpreter is built with. However, you may not be able to use Visual Studio, for following reasons:

1. VS is proprietary and commercial software. Microsoft provides a freeware “Community” edition, but its licensing terms impose restrictions as to where and how it can be used.
2. Visual Studio contains telemetry, as documented in [Microsoft Visual Studio Licensing Terms](#). Running software with telemetry may be against the policy of your organization.

So you may want to build XGBoost with GCC own your own risk. This presents some difficulties because MSVC uses Microsoft runtime and MinGW-w64 uses own runtime, and the runtimes have different incompatible memory allocators. But in fact this setup is usable if you know how to deal with it. Here is some experience.

1. The Python interpreter will crash on exit if XGBoost was used. This is usually not a big issue.
2. `-O3` is OK.
3. `-mtune=native` is also OK.
4. Don’t use `-march=native` gcc flag. Using it causes the Python interpreter to crash if the DLL was actually used.
5. You may need to provide the lib with the runtime libs. If `mingw32/bin` is not in PATH, build a wheel (`pip wheel`), open it with an archiver and put the needed dlls to the directory where `xgboost.dll` is situated. Then you can install the wheel with `pip`.

#### 1.2.4 Building R Package From Source

By default, the package installed by running `install.packages` is built from source. Here we list some other options for installing development version.
Installing the development version (Linux / Mac OSX)

Make sure you have installed git and a recent C++ compiler supporting C++11 (See above sections for requirements of building C++ core).

Due to the use of git-submodules, `remotes::install_github()` cannot be used to install the latest version of R package. Thus, one has to run git to check out the code first, see Obtaining the Source Code on how to initialize the git repository for XGBoost. The simplest way to install the R package after obtaining the source code is:

```
cd R-package
R CMD INSTALL .
```

But if you want to use CMake build for better performance (which has the logic for detecting available CPU instructions) or greater flexibility around compile flags, the above snippet can be replaced by:

```
mkdir build
cd build
cmake .. -DR_LIB=ON
make -j$(nproc)
make install
```

Installing the development version with Visual Studio (Windows)

On Windows, CMake with Visual C++ Build Tools (or Visual Studio) can be used to build the R package. While not required, this build can be faster if you install the R package `processx` with `install.packages("processx")`.

**Note**

Setting correct PATH environment variable on Windows

If you are using Windows, make sure to include the right directories in the PATH environment variable.

- If you are using R 4.x with RTools 4.0: `-C:\rtools40\usr\bin -C:\rtools40\mingw64\bin`
- If you are using R 3.x with RTools 3.x:
  - `-C:\Rtools\bin`
  - `-C:\Rtools\mingw_64\bin`

Open the Command Prompt and navigate to the XGBoost directory, and then run the following commands. Make sure to specify the correct R version.

```
cd C:\path\to\xgboost
mkdir build
cd build
cmake .. -G"Visual Studio 16 2019" -A x64 -DR_LIB=ON -DR_VERSION=4.0.0
make --build . --target install --config Release
```
Building R package with GPU support

The procedure and requirements are similar as in Building with GPU support, so make sure to read it first.

On Linux, starting from the XGBoost directory type:

```bash
mkdir build
cd build
cmake .. -DUSE_CUDA=ON -DR_LIB=ON
make install -j$(nproc)
```

When default target is used, an R package shared library would be built in the build area. The install target, in addition, assembles the package files with this shared library under build/R-package and runs `R CMD INSTALL`.

On Windows, CMake with Visual Studio has to be used to build an R package with GPU support. Rtools must also be installed.

---

### Note

**Setting correct PATH environment variable on Windows**

If you are using Windows, make sure to include the right directories in the PATH environment variable.

- If you are using R 4.x with RTools 4.0:
  - C:\rtools40\usr\bin
  - C:\rtools40\mingw64\bin
- If you are using R 3.x with RTools 3.x:
  - C:\Rtools\bin
  - C:\Rtools\mingw_64\bin

Open the Command Prompt and navigate to the XGBoost directory, and then run the following commands. Make sure to specify the correct R version.

```bash
cd C:\path\to\xgboost
mkdir build
cd build
cmake .. -G"Visual Studio 16 2019" -A x64 -DUSE_CUDA=ON -DR_LIB=ON -DR_VERSION=4.0.0
cmake --build . --target install --config Release
```

If CMake can’t find your R during the configuration step, you might provide the location of R to CMake like this: `-DLIBR_HOME=C:\Program Files\R\R-4.0.0`.

If on Windows you get a “permission denied” error when trying to write to Program Files/R/... during the package installation, create a `.Rprofile` file in your personal home directory (if you don’t already have one in there), and add a line to it which specifies the location of your R packages user library, like the following:

```r
.libPaths( unique(c("C:/Users/USERNAME/Documents/R/win-library/3.4", .libPaths())))
```

You might find the exact location by running `.libPaths()` in R GUI or RStudio.
1.2.5 Building JVM Packages

Building XGBoost4J using Maven requires Maven 3 or newer, Java 7+ and CMake 3.13+ for compiling Java code as well as the Java Native Interface (JNI) bindings.

Before you install XGBoost4J, you need to define environment variable JAVA_HOME as your JDK directory to ensure that your compiler can find jni.h correctly, since XGBoost4J relies on JNI to implement the interaction between the JVM and native libraries.

After your JAVA_HOME is defined correctly, it is as simple as run mvn package under jvm-packages directory to install XGBoost4J. You can also skip the tests by running mvn -DskipTests=true package, if you are sure about the correctness of your local setup.

To publish the artifacts to your local maven repository, run

```
mvn install
```

Or, if you would like to skip tests, run

```
mvn -DskipTests install
```

This command will publish the xgboost binaries, the compiled java classes as well as the java sources to your local repository. Then you can use XGBoost4J in your Java projects by including the following dependency in pom.xml:

```
<dependency>
  <groupId>ml.dmlc</groupId>
  <artifactId>xgboost4j</artifactId>
  <version>latest_source_version_num</version>
</dependency>
```

For sbt, please add the repository and dependency in build.sbt as following:

```
resolvers += "Local Maven Repository" at "file://"+Path.userHome.absolutePath+"/.m2/repositories"

"ml.dmlc" % "xgboost4j" % "latest_source_version_num"
```

If you want to use XGBoost4J-Spark, replace xgboost4j with xgboost4j-spark.

⚠️ Note

XGBoost4J-Spark requires Apache Spark 2.3+

XGBoost4J-Spark now requires Apache Spark 2.3+. Latest versions of XGBoost4J-Spark uses facilities of org.apache.spark.ml.param.shared extensively to provide for a tight integration with Spark MLLIB framework, and these facilities are not fully available on earlier versions of Spark.

Also, make sure to install Spark directly from Apache website. **Upstream XGBoost is not guaranteed to work with third-party distributions of Spark, such as Cloudera Spark.** Consult appropriate third parties to obtain their distribution of XGBoost.
Enabling OpenMP for Mac OS

If you are on Mac OS and using a compiler that supports OpenMP, you need to go to the file `xgboost/jvm-packages/create_jni.py` and comment out the line

```
CONFIG["USE_OPENMP"] = "OFF"
```

in order to get the benefit of multi-threading.

Building with GPU support

If you want to build XGBoost4J that supports distributed GPU training, run

```
mvn -Duse.cuda=ON install
```

1.2.6 Building the Documentation

XGBoost uses Sphinx for documentation. To build it locally, you need a installed XGBoost with all its dependencies along with:

- System dependencies
  - git
  - graphviz
- Python dependencies

Checkout the `requirements.txt` file under `doc/`

Under `xgboost/doc` directory, run `make <format>` with `<format>` replaced by the format you want. For a list of supported formats, run `make help` under the same directory.

1.3 Get Started with XGBoost

This is a quick start tutorial showing snippets for you to quickly try out XGBoost on the demo dataset on a binary classification task.

1.3.1 Links to Other Helpful Resources

- See Installation Guide on how to install XGBoost.
- See Text Input Format on using text format for specifying training/testing data.
- See Tutorials for tips and tutorials.
- See Learning to use XGBoost by Examples for more code examples.
1.3.2 Python

```python
from xgboost import XGBClassifier
# read data
from sklearn.datasets import load_iris
from sklearn.model_selection import train_test_split
data = load_iris()
X_train, X_test, y_train, y_test = train_test_split(data['data'], data['target'], test_size=.2)
# create model instance
bst = XGBClassifier(n_estimators=2, max_depth=2, learning_rate=1, objective='binary:logistic')
# fit model
bst.fit(X_train, y_train)
# make predictions
preds = bst.predict(X_test)
```

1.3.3 R

```r
# load data
data(agaricus.train, package='xgboost')
data(agaricus.test, package='xgboost')
train <- agaricus.train
test <- agaricus.test
# fit model
bst <- xgboost(data = train$data, label = train$label, max.depth = 2, eta = 1, nrounds = 2, nthread = 2, objective = "binary:logistic")
# predict
pred <- predict(bst, test$data)
```

1.3.4 Julia

```julia
using XGBoost
# read data
train_X, train_Y = readlibsvm("demo/data/agaricus.txt.train", (6513, 126))
test_X, test_Y = readlibsvm("demo/data/agaricus.txt.test", (1611, 126))
# fit model
num_round = 2
bst = xgboost(train_X, num_round, label=train_Y, eta=1, max_depth=2)
# predict
pred = predict(bst, test_X)
```
1.3.5 Scala

```scala
import ml.dmlc.xgboost4j.scala.DMatrix
import ml.dmlc.xgboost4j.scala.XGBoost

object XGBoostScalaExample {
  def main(args: Array[String]) {
    // read training data, available at xgboost/demo/data
    val trainData = new DMatrix("/path/to/agaricus.txt.train")
    // define parameters
    val paramMap = List(
      "eta" -> 0.1,
      "max_depth" -> 2,
      "objective" -> "binary:logistic").toMap
    // number of iterations
    val round = 2
    // train the model
    val model = XGBoost.train(trainData, paramMap, round)
    // run prediction
    val predTrain = model.predict(trainData)
    // save model to the file.
    model.saveModel("/local/path/to/model")
  }
}
```

1.4 XGBoost Tutorials

This section contains official tutorials inside XGBoost package. See Awesome XGBoost for more resources. Also, don’t miss the feature introductions in each package.

1.4.1 Introduction to Boosted Trees

XGBoost stands for “Extreme Gradient Boosting”, where the term “Gradient Boosting” originates from the paper *Greedy Function Approximation: A Gradient Boosting Machine*, by Friedman.

The gradient boosted trees has been around for a while, and there are a lot of materials on the topic. This tutorial will explain boosted trees in a self-contained and principled way using the elements of supervised learning. We think this explanation is cleaner, more formal, and motivates the model formulation used in XGBoost.

Elements of Supervised Learning

XGBoost is used for supervised learning problems, where we use the training data (with multiple features) $x_i$ to predict a target variable $y_i$. Before we learn about trees specifically, let us start by reviewing the basic elements in supervised learning.
Model and Parameters

The model in supervised learning usually refers to the mathematical structure of by which the prediction $y_i$ is made from the input $x_i$. A common example is a linear model, where the prediction is given as $\hat{y}_i = \sum_j \theta_j x_{ij}$, a linear combination of weighted input features. The prediction value can have different interpretations, depending on the task, i.e., regression or classification. For example, it can be logistic transformed to get the probability of positive class in logistic regression, and it can also be used as a ranking score when we want to rank the outputs.

The parameters are the undetermined part that we need to learn from data. In linear regression problems, the parameters are the coefficients $\theta$. Usually we will use $\theta$ to denote the parameters (there are many parameters in a model, our definition here is sloppy).

Objective Function: Training Loss + Regularization

With judicious choices for $y_i$, we may express a variety of tasks, such as regression, classification, and ranking. The task of training the model amounts to finding the best parameters $\theta$ that best fit the training data $x_i$ and labels $y_i$. In order to train the model, we need to define the objective function to measure how well the model fit the training data.

A salient characteristic of objective functions is that they consist of two parts: training loss and regularization term:

$$\text{obj}(\theta) = L(\theta) + \Omega(\theta)$$

where $L$ is the training loss function, and $\Omega$ is the regularization term. The training loss measures how predictive our model is with respect to the training data. A common choice of $L$ is the mean squared error, which is given by

$$L(\theta) = \sum_i (y_i - \hat{y}_i)^2$$

Another commonly used loss function is logistic loss, to be used for logistic regression:

$$L(\theta) = \sum_i [y_i \ln(1 + e^{-\hat{y}_i}) + (1 - y_i) \ln(1 + e^{\hat{y}_i})]$$

The regularization term is what people usually forget to add. The regularization term controls the complexity of the model, which helps us to avoid overfitting. This sounds a bit abstract, so let us consider the following problem in the following picture. You are asked to fit visually a step function given the input data points on the upper left corner of the image. Which solution among the three do you think is the best fit?
The correct answer is marked in red. Please consider if this visually seems a reasonable fit to you. The general principle is we want both a simple and predictive model. The tradeoff between the two is also referred as bias-variance tradeoff in machine learning.

**Why introduce the general principle?**

The elements introduced above form the basic elements of supervised learning, and they are natural building blocks of machine learning toolkits. For example, you should be able to describe the differences and commonalities between gradient boosted trees and random forests. Understanding the process in a formalized way also helps us to understand the objective that we are learning and the reason behind the heuristics such as pruning and smoothing.
Decision Tree Ensembles

Now that we have introduced the elements of supervised learning, let us get started with real trees. To begin with, let us first learn about the model choice of XGBoost: decision tree ensembles. The tree ensemble model consists of a set of classification and regression trees (CART). Here’s a simple example of a CART that classifies whether someone will like a hypothetical computer game X.

We classify the members of a family into different leaves, and assign them the score on the corresponding leaf. A CART is a bit different from decision trees, in which the leaf only contains decision values. In CART, a real score is associated with each of the leaves, which gives us richer interpretations that go beyond classification. This also allows for a principled, unified approach to optimization, as we will see in a later part of this tutorial.

Usually, a single tree is not strong enough to be used in practice. What is actually used is the ensemble model, which sums the prediction of multiple trees together.

Here is an example of a tree ensemble of two trees. The prediction scores of each individual tree are summed up to
get the final score. If you look at the example, an important fact is that the two trees try to complement each other. Mathematically, we can write our model in the form

\[ \hat{y}_i = \sum_{k=1}^{K} f_k(x_i), f_k \in \mathcal{F} \]

where \( K \) is the number of trees, \( f_k \) is a function in the functional space \( \mathcal{F} \), and \( \mathcal{F} \) is the set of all possible CARTs. The objective function to be optimized is given by

\[ \text{obj}(\theta) = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{k=1}^{K} \omega(f_k) \]

where \( \omega(f_k) \) is the complexity of the tree \( f_k \), defined in detail later.

Now here comes a trick question: what is the model used in random forests? Tree ensembles! So random forests and boosted trees are really the same models; the difference arises from how we train them. This means that, if you write a predictive service for tree ensembles, you only need to write one and it should work for both random forests and gradient boosted trees. (See Treelite for an actual example.) One example of why elements of supervised learning rock.

**Tree Boosting**

Now that we introduced the model, let us turn to training: How should we learn the trees? The answer is, as is always for all supervised learning models: define an objective function and optimize it!

Let the following be the objective function (remember it always needs to contain training loss and regularization):

\[ \text{obj} = \sum_{i=1}^{n} l(y_i, \hat{y}_i^{(t)}) + \sum_{i=1}^{t} \omega(f_i) \]

**Additive Training**

The first question we want to ask: what are the parameters of trees? You can find that what we need to learn are those functions \( f_i \), each containing the structure of the tree and the leaf scores. Learning tree structure is much harder than traditional optimization problem where you can simply take the gradient. It is intractable to learn all the trees at once. Instead, we use an additive strategy: fix what we have learned, and add one new tree at a time. We write the prediction value at step \( t \) as \( \hat{y}_i^{(t)} \). Then we have

\[ \hat{y}_i^{(0)} = 0 \]
\[ \hat{y}_i^{(1)} = f_1(x_i) = \hat{y}_i^{(0)} + f_1(x_i) \]
\[ \hat{y}_i^{(2)} = f_1(x_i) + f_2(x_i) = \hat{y}_i^{(1)} + f_2(x_i) \]
\[ \vdots \]
\[ \hat{y}_i^{(t)} = \sum_{k=1}^{t} f_k(x_i) = \hat{y}_i^{(t-1)} + f_t(x_i) \]

It remains to ask: which tree do we want at each step? A natural thing is to add the one that optimizes our objective.

\[ \text{obj}^{(t)} = \sum_{i=1}^{n} l(y_i, \hat{y}_i^{(t)}) + \sum_{i=1}^{t} \omega(f_i) \]
\[ = \sum_{i=1}^{n} l(y_i, \hat{y}_i^{(t-1)} + f_t(x_i)) + \omega(f_t) + \text{constant} \]
If we consider using mean squared error (MSE) as our loss function, the objective becomes

\[
\text{obj}(t) = \sum_{i=1}^{n} (y_i - (\hat{y}_i^{(t-1)} + f_t(x_i)))^2 + \sum_{i=1}^{t} \omega(f_t)
\]

\[
= \sum_{i=1}^{n} [2(\hat{y}_i^{(t-1)} - y_i)f_t(x_i) + f_t(x_i)^2] + \omega(f_t) + \text{constant}
\]

The form of MSE is friendly, with a first order term (usually called the residual) and a quadratic term. For other losses of interest (for example, logistic loss), it is not so easy to get such a nice form. So in the general case, we take the Taylor expansion of the loss function up to the second order:

\[
\text{obj}(t) = \sum_{i=1}^{n} \left[l(y_i, \hat{y}_i^{(t-1)}) + g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i)\right] + \omega(f_t) + \text{constant}
\]

where the \(g_i\) and \(h_i\) are defined as

\[
g_i = \partial_{\hat{y}_i^{(t-1)}} l(y_i, \hat{y}_i^{(t-1)})
\]

\[
h_i = \partial^2_{\hat{y}_i^{(t-1)}} l(y_i, \hat{y}_i^{(t-1)})
\]

After we remove all the constants, the specific objective at step \(t\) becomes

\[
\sum_{i=1}^{n} [g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i)] + \omega(f_t)
\]

This becomes our optimization goal for the new tree. One important advantage of this definition is that the value of the objective function only depends on \(g_i\) and \(h_i\). This is how XGBoost supports custom loss functions. We can optimize every loss function, including logistic regression and pairwise ranking, using exactly the same solver that takes \(g_i\) and \(h_i\) as input!

**Model Complexity**

We have introduced the training step, but wait, there is one important thing, the **regularization term**! We need to define the complexity of the tree \(\omega(f)\). In order to do so, let us first refine the definition of the tree \(f(x)\) as

\[
f_t(x) = w_{q(x)}, w \in R^T, q : R^d \rightarrow \{1, 2, \cdots, T\}.
\]

Here \(w\) is the vector of scores on leaves, \(q\) is a function assigning each data point to the corresponding leaf, and \(T\) is the number of leaves. In XGBoost, we define the complexity as

\[
\omega(f) = \gamma T + \frac{1}{2} \lambda \sum_{j=1}^{T} w_j^2
\]

Of course, there is more than one way to define the complexity, but this one works well in practice. The regularization is one part most tree packages treat less carefully, or simply ignore. This was because the traditional treatment of tree learning only emphasized improving impurity, while the complexity control was left to heuristics. By defining it formally, we can get a better idea of what we are learning and obtain models that perform well in the wild.
The Structure Score

Here is the magical part of the derivation. After re-formulating the tree model, we can write the objective value with the \( t \)-th tree as:

\[
\text{obj}^{(t)} \approx \sum_{i=1}^{n} [g_i w_{q(x_i)} + \frac{1}{2} h_i w_{q(x_i)}^2] + \gamma T + \frac{1}{2} \lambda \sum_{j=1}^{T} w_j^2
\]

\[
= \sum_{j=1}^{T} [(\sum_{i \in I_j} g_i) w_j + \frac{1}{2} (\sum_{i \in I_j} h_i + \lambda) w_j^2] + \gamma T
\]

where \( I_j = \{i | q(x_i) = j\} \) is the set of indices of data points assigned to the \( j \)-th leaf. Notice that in the second line we have changed the index of the summation because all the data points on the same leaf get the same score. We could further compress the expression by defining \( G_j = \sum_{i \in I_j} g_i \) and \( H_j = \sum_{i \in I_j} h_i \):

\[
\text{obj}^{(t)} = \sum_{j=1}^{T} [G_j w_j + \frac{1}{2} (H_j + \lambda) w_j^2] + \gamma T
\]

In this equation, \( w_j \) are independent with respect to each other, the form \( G_j w_j + \frac{1}{2} (H_j + \lambda) w_j^2 \) is quadratic and the best \( w_j \) for a given structure \( q(x) \) and the best objective reduction we can get is:

\[
w_j^* = - \frac{G_j}{H_j + \lambda}
\]

\[
\text{obj}^* = - \frac{1}{2} \sum_{j=1}^{T} \frac{G_j^2}{H_j + \lambda} + \gamma T
\]

The last equation measures how good a tree structure \( q(x) \) is.

If all this sounds a bit complicated, let’s take a look at the picture, and see how the scores can be calculated. Basically, for a given tree structure, we push the statistics \( g_i \) and \( h_i \) to the leaves they belong to, sum the statistics together, and use the formula to calculate how good the tree is. This score is like the impurity measure in a decision tree, except that it also takes the model complexity into account.
Learn the tree structure

Now that we have a way to measure how good a tree is, ideally we would enumerate all possible trees and pick the best one. In practice this is intractable, so we will try to optimize one level of the tree at a time. Specifically we try to split a leaf into two leaves, and the score it gains is

$$\text{Gain} = \frac{1}{2} \left[ \frac{G_L^2}{H_L + \lambda} + \frac{G_R^2}{H_R + \lambda} - \frac{(G_L + G_R)^2}{H_L + H_R + \lambda} \right] - \gamma$$

This formula can be decomposed as 1) the score on the new left leaf 2) the score on the new right leaf 3) The score on the original leaf 4) regularization on the additional leaf. We can see an important fact here: if the gain is smaller than $\gamma$, we would do better not to add that branch. This is exactly the pruning techniques in tree based models! By using the principles of supervised learning, we can naturally come up with the reason these techniques work :) For real valued data, we usually want to search for an optimal split. To efficiently do so, we place all the instances in sorted order, like the following picture.

A left to right scan is sufficient to calculate the structure score of all possible split solutions, and we can find the best split efficiently.

### Note

**Limitation of additive tree learning**

Since it is intractable to enumerate all possible tree structures, we add one split at a time. This approach works well most of the time, but there are some edge cases that fail due to this approach. For those edge cases, training results in a degenerate model because we consider only one feature dimension at a time. See Can Gradient Boosting Learn Simple Arithmetic? for an example.

### Final words on XGBoost

Now that you understand what boosted trees are, you may ask, where is the introduction for XGBoost? XGBoost is exactly a tool motivated by the formal principle introduced in this tutorial! More importantly, it is developed with both deep consideration in terms of systems optimization and principles in machine learning. The goal of this library is to push the extreme of the computation limits of machines to provide a scalable, portable and accurate library. Make sure you try it out, and most importantly, contribute your piece of wisdom (code, examples, tutorials) to the community!
1.4.2 Introduction to Model IO

Since 2.1.0, the default model format for XGBoost is the UBJSON format, the option is enabled for serializing models to file, serializing models to buffer, and for memory snapshot (pickle and alike).

In XGBoost 1.0.0, we introduced support of using JSON for saving/loading XGBoost models and related hyperparameters for training, aiming to replace the old binary internal format with an open format that can be easily reused. Later in XGBoost 1.6.0, additional support for Universal Binary JSON is added as an optimization for more efficient model IO, which is set to default in 2.1.

JSON and UBJSON have the same document structure with different representations, and we will refer them collectively as the JSON format. This tutorial aims to share some basic insights into the JSON serialization method used in XGBoost. Without explicitly mentioned, the following sections assume you are using the one of the 2 outputs formats, which can be enabled by providing the file name with .json (or .ubj for binary JSON) as file extension when saving/loading model: booster.save_model('model.json'). More details below.

Before we get started, XGBoost is a gradient boosting library with focus on tree model, which means inside XGBoost, there are 2 distinct parts:

1. The model consisting of trees and
2. Hyperparameters and configurations used for building the model.

If you come from Deep Learning community, then it should be clear to you that there are differences between the neural network structures composed of weights with fixed tensor operations, and the optimizers (like RMSprop) used to train them.

So when one calls booster.save_model (xgb.save in R), XGBoost saves the trees, some model parameters like number of input columns in trained trees, and the objective function, which combined to represent the concept of “model” in XGBoost. As for why are we saving the objective as part of model, that’s because objective controls transformation of global bias (called base_score in XGBoost) and task-specific information. Users can share this model with others for prediction, evaluation or continue the training with a different set of hyper-parameters etc.

However, this is not the end of story. There are cases where we need to save something more than just the model itself. For example, in distributed training, XGBoost performs checkpointing operation. Or for some reasons, your favorite distributed computing framework decide to copy the model from one worker to another and continue the training in there. In such cases, the serialisation output is required to contain enough information to continue previous training without user providing any parameters again. We consider such scenario as memory snapshot (or memory based serialisation method) and distinguish it with normal model IO operation. Currently, memory snapshot is used in the following places:

- Python package: when the Booster object is pickled with the built-in pickle module.
- R package: when the xgb.Booster object is persisted with the built-in functions saveRDS or save.
- JVM packages: when the Booster object is serialized with the built-in functions saveModel.

Other language bindings are still working in progress.

Note

The old binary format doesn’t distinguish difference between model and raw memory serialisation format, it’s a mix of everything, which is part of the reason why we want to replace it with a more robust serialisation method. JVM Package has its own memory based serialisation methods.

To enable JSON format support for model IO (saving only the trees and objective), provide a filename with .json or .ubj as file extension, the latter is the extension for Universal Binary JSON.
Listing 11: Python

```python
bst.save_model('model_file_name.json')
```

Listing 12: R

```r
xgb.save(bst, 'model_file_name.json')
```

Listing 13: Scala

```scala
val format = "json" // or val format = "ubj"
model.write.option("format", format).save("model_directory_path")
```

Note

Only load models from JSON files that were produced by XGBoost. Attempting to load JSON files that were produced by an external source may lead to undefined behaviors and crashes.

While for memory snapshot, UBJSON is the default starting with xgboost 1.6. When loading the model back, XGBoost recognizes the file extensions .json and .ubj, and can dispatch accordingly. If the extension is not specified, XGBoost tries to guess the right one.

A note on backward compatibility of models and memory snapshots

We guarantee backward compatibility for models but not for memory snapshots.

Models (trees and objective) use a stable representation, so that models produced in earlier versions of XGBoost are accessible in later versions of XGBoost. If you’d like to store or archive your model for long-term storage, use save_model (Python) and xgb.save (R).

On the other hand, memory snapshot (serialisation) captures many stuff internal to XGBoost, and its format is not stable and is subject to frequent changes. Therefore, memory snapshot is suitable for checkpointing only, where you persist the complete snapshot of the training configurations so that you can recover robustly from possible failures and resume the training process. Loading memory snapshot generated by an earlier version of XGBoost may result in errors or undefined behaviors. If a model is persisted with pickle.dump (Python) or saveRDS (R), then the model may not be accessible in later versions of XGBoost.

Custom objective and metric

XGBoost accepts user provided objective and metric functions as an extension. These functions are not saved in model file as they are language dependent features. With Python, user can pickle the model to include these functions in saved binary. One drawback is, the output from pickle is not a stable serialization format and doesn’t work on different Python version nor XGBoost version, not to mention different language environments. Another way to workaround this limitation is to provide these functions again after the model is loaded. If the customized function is useful, please consider making a PR for implementing it inside XGBoost, this way we can have your functions working with different language bindings.
Loading pickled file from different version of XGBoost

As noted, pickled model is neither portable nor stable, but in some cases the pickled models are valuable. One way to restore it in the future is to load it back with that specific version of Python and XGBoost, export the model by calling `save_model`.

A similar procedure may be used to recover the model persisted in an old RDS file. In R, you are able to install an older version of XGBoost using the `remotes` package:

```r
library(remotes)
remotes::install_version("xgboost", "0.90.0.1")  # Install version 0.90.0.1
```

Once the desired version is installed, you can load the RDS file with `readRDS` and recover the `xgb.Booster` object. Then call `xgb.save` to export the model using the stable representation. Now you should be able to use the model in the latest version of XGBoost.

Saving and Loading the internal parameters configuration

XGBoost’s C API, Python API and R API support saving and loading the internal configuration directly as a JSON string. In Python package:

```python
bst = xgboost.train(...)  
config = bst.save_config()  
print(config)
```

or in R:

```r
config <- xgb.config(bst)  
print(config)
```

Will print out something similar to (not actual output as it’s too long for demonstration):

```json
{
  "Learner": {
    "generic_parameter": {
      "device": "cuda:0",
      "gpu_page_size": "0",
      "n_jobs": "0",
      "random_state": "0",
      "seed": "0",
      "seed_per_iteration": "0"
    },
    "gradient_booster": {
      "gbtree_train_param": {
        "num_parallel_tree": "1",
        "process_type": "default",
        "tree_method": "hist",
        "updater": "grow_gpu_hist",
        "updater_seq": "grow_gpu_hist"
      },
      "name": "gbtree",
      "updater": {
        "grow_gpu_hist": {
          "gpu_hist_train_param": {
...
```
"debug_synchronize": "0",
},
"train_param": {
"alpha": "0",
"cache_opt": "1",
"colsample_bylevel": "1",
"colsample_bynode": "1",
"colsample_bytree": "1",
"default_direction": "learn",
...

"subsample": "1"
}
}

"learner_train_param": {
"booster": "gbtree",
"disable_default_eval_metric": "0",
"objective": "reg:squarederror"
},
"metrics": [],
"objective": {
"name": "reg:squarederror",
"reg_loss_param": {
"scale_pos_weight": "1"
}
}
},
"version": [1, 0, 0]
}

You can load it back to the model generated by same version of XGBoost by:

```
bst.load_config(config)
```

This way users can study the internal representation more closely. Please note that some JSON generators make use of locale dependent floating point serialization methods, which is not supported by XGBoost.
Difference between saving model and dumping model

XGBoost has a function called dump_model in Booster object, which lets you to export the model in a readable format like text, json or dot (graphviz). The primary use case for it is for model interpretation or visualization, and is not supposed to be loaded back to XGBoost. The JSON version has a schema. See next section for more info.

JSON Schema

Another important feature of JSON format is a documented schema, based on which one can easily reuse the output model from XGBoost. Here is the JSON schema for the output model (not serialization, which will not be stable as noted above). For an example of parsing XGBoost tree model, see /demo/json-model. Please notice the “weight_drop” field used in “dart” booster. XGBoost does not scale tree leaf directly, instead it saves the weights as a separated array.

```json
{
    "$schema": "http://json-schema.org/draft-07/schema#",
    "definitions": {
        "gbtree": {
            "type": "object",
            "properties": {
                "name": {

Overview

Often in the context of information retrieval, learning-to-rank aims to train a model that arranges a set of query results into an ordered list [1]. For supervised learning-to-rank, the predictors are sample documents encoded as feature matrix, and the labels are relevance degree for each sample. Relevance degree can be multi-level (graded) or binary (relevant or not). The training samples are often grouped by their query index with each query group containing multiple query results.

XGBoost implements learning to rank through a set of objective functions and performance metrics. The default objective is `rank:ndcg` based on the LambdaMART [2] algorithm, which in turn is an adaptation of the LambdaRank [3] framework to gradient boosting trees. For a history and a summary of the algorithm, see [5]. The implementation in XGBoost features deterministic GPU computation, distributed training, position debiasing and two different pair construction strategies.

Training with the Pairwise Objective

LambdaMART is a pairwise ranking model, meaning that it compares the relevance degree for every pair of samples in a query group and calculate a proxy gradient for each pair. The default objective `rank:ndcg` is using the surrogate gradient derived from the `ndcg` metric. To train a XGBoost model, we need an additional sorted array called `qid` for specifying the query group of input samples. An example input would look like this:

<table>
<thead>
<tr>
<th>QID</th>
<th>Label</th>
<th>Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>$x_1$</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>$x_2$</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>$x_3$</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>$x_4$</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>$x_5$</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>$x_6$</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>$x_7$</td>
</tr>
</tbody>
</table>

Notice that the samples are sorted based on their query index in a non-decreasing order. In the above example, the
The simplest way to train a ranking model is by using the scikit-learn estimator interface. Continuing the previous snippet, we can train a simple ranking model without tuning:

```python
ranker = xgb.XGBRanker(tree_method="hist", lambdarank_num_pair_per_sample=8, objective="rank:ndcg", lambdarank_pair_method="topk")
ranker.fit(X, y, qid=qid)
```

Please note that, as of writing, there's no learning-to-rank interface in scikit-learn. As a result, the `xgboost.XGBRanker` class does not fully conform to the scikit-learn estimator guideline and cannot be directly used with some of its utility functions. For instances, the `auc_score` and `ndcg_score` in scikit-learn don’t consider query group information nor the pairwise loss. Most of the metrics are implemented as part of XGBoost, but to use scikit-learn utilities like `sklearn.model_selection.cross_validation()`, we need to make some adjustments in order to pass the `qid` as an additional parameter for `xgboost.XGBRanker.score()`. Given a data frame `X` (either pandas or cuDF), add the column `qid` as follows:

```python
import pandas as pd

# `X`, `qid`, and `y` are from the previous snippet, they are all sorted by the `sorted_idx`
df = pd.DataFrame(X, columns=[str(i) for i in range(X.shape[1])])
df["qid"] = qid

ranker.fit(df, y)  # No need to pass qid as a separate argument
```

The above snippets build a model using LambdaMART with the NDCG@8 metric. The outputs of a ranker are relevance scores:
scores = ranker.predict(X)
sorted_idx = np.argsort(scores)[::-1]
# Sort the relevance scores from most relevant to least relevant
scores = scores[sorted_idx]

**Position Bias**

Added in version 2.0.0.

> **Note**

The feature is considered experimental. This is a heated research area, and your input is much appreciated!

Obtaining real relevance degrees for query results is an expensive and strenuous, requiring human labelers to label all results one by one. When such labeling task is infeasible, we might want to train the learning-to-rank model on user click data instead, as it is relatively easy to collect. Another advantage of using click data directly is that it can reflect the most up-to-date user preferences [1]. However, user clicks are often biased, as users tend to choose results that are displayed in higher positions. User clicks are also noisy, where users might accidentally click on irrelevant documents. To ameliorate these issues, XGBoost implements the Unbiased LambdaMART [4] algorithm to debias the position-dependent click data. The feature can be enabled by the `lambdarank_unbiased` parameter; see Parameters for learning to rank (rank:ndcg, rank:map, rank:pairwise) for related options and Getting started with learning to rank for a worked example with simulated user clicks.

**Loss**

XGBoost implements different LambdaMART objectives based on different metrics. We list them here as a reference. Other than those used as objective function, XGBoost also implements metrics like pre (for precision) for evaluation. See parameters for available options and the following sections for how to choose these objectives based on the amount of effective pairs.

- **NDCG**

  Normalized Discounted Cumulative Gain (NDCG) can be used with both binary relevance and multi-level relevance. If you are not sure about your data, this metric can be used as the default. The name for the objective is `rank:ndcg`.

- **MAP**

  Mean average precision (MAP) is a binary measure. It can be used when the relevance label is 0 or 1. The name for the objective is `rank:map`.

- **Pairwise**

  The LambdaMART algorithm scales the logistic loss with learning to rank metrics like NDCG in the hope of including ranking information into the loss function. The `rank:pairwise` loss is the original version of the pairwise loss, also known as the RankNet loss [7] or the pairwise logistic loss. Unlike the `rank:map` and the `rank:ndcg`, no scaling is applied (|ΔZij| = 1).

  Whether scaling with a LTR metric is actually more effective is still up for debate; [8] provides a theoretical foundation for general lambda loss functions and some insights into the framework.
Constructing Pairs

There are two implemented strategies for constructing document pairs for \( \lambda \)-gradient calculation. The first one is the mean method, another one is the topk method. The preferred strategy can be specified by the lambdarank_pair_method parameter.

For the mean strategy, XGBoost samples lambdarank_num_pair_per_sample pairs for each document in a query list. For example, given a list of 3 documents and lambdarank_num_pair_per_sample is set to 2, XGBoost will randomly sample 6 pairs, assuming the labels for these documents are different. On the other hand, if the pair method is set to topk, XGBoost constructs about \( k \times |query| \) number of pairs with \( |query| \) pairs for each sample at the top \( k = \text{lambdarank}_\text{num_pair_position} \). The number of pairs counted here is an approximation since we skip pairs that have the same label.

Obtaining Good Result

Learning to rank is a sophisticated task and an active research area. It’s not trivial to train a model that generalizes well. There are multiple loss functions available in XGBoost along with a set of hyperparameters. This section contains some hints for how to choose hyperparameters as a starting point. One can further optimize the model by tuning these hyperparameters.

The first question would be how to choose an objective that matches the task at hand. If your input data has multi-level relevance degrees, then either rank:ndcg or rank:pairwise should be used. However, when the input has binary labels, we have multiple options based on the target metric. [6] provides some guidelines on this topic and users are encouraged to see the analysis done in their work. The choice should be based on the number of effective pairs, which refers to the number of pairs that can generate non-zero gradient and contribute to training. LambdaMART with MRR has the least amount of effective pairs as the \( \lambda \)-gradient is only non-zero when the pair contains a non-relevant document ranked higher than the top relevant document. As a result, it’s not implemented in XGBoost. Since NDCG is a multi-level metric, it usually generate more effective pairs than MAP.

However, when there are sufficiently many effective pairs, it’s shown in [6] that matching the target metric with the objective is of significance. When the target metric is MAP and you are using a large dataset that can provide a sufficient amount of effective pairs, rank:map can in theory yield higher MAP value than rank:ndcg.

The consideration of effective pairs also applies to the choice of pair method (lambdarank_pair_method) and the number of pairs for each sample (lambdarank_num_pair_per_sample). For example, the mean-NDCG considers more pairs than NDCG@10, so the former generates more effective pairs and provides more granularity than the latter. Also, using the mean strategy can help the model generalize with random sampling. However, one might want to focus the training on the top \( k \) documents instead of using all pairs, to better fit their real-world application.

When using the mean strategy for generating pairs, where the target metric (like NDCG) is computed over the whole query list, users can specify how many pairs should be generated per each document, by setting the lambdarank_num_pair_per_sample. XGBoost will randomly sample lambdarank_num_pair_per_sample pairs for each element in the query group (\(|pairs| = |query| \times \text{num_pairsample}\)). Often, setting it to 1 can produce reasonable results. In cases where performance is inadequate due to insufficient number of effective pairs being generated, set lambdarank_num_pair_per_sample to a higher value. As more document pairs are generated, more effective pairs will be generated as well.

On the other hand, if you are prioritizing the top \( k \) documents, the lambdarank_num_pair_per_sample should be set slightly higher than \( k \) (with a few more documents) to obtain a good training result. Lastly, XGBoost employs additional regularization for learning to rank objectives, which can be disabled by setting the lambdarank_normalization to False.

Summary If you have large amount of training data:

- Use the target-matching objective.
- Choose the topk strategy for generating document pairs (if it’s appropriate for your application).
On the other hand, if you have comparatively small amount of training data:

- Select NDCG or the RankNet loss (`rank:pairwise`).
- Choose the mean strategy for generating document pairs, to obtain more effective pairs.

For any method chosen, you can modify `lambdarank_num_pair_per_sample` to control the amount of pairs generated.

**Distributed Training**

XGBoost implements distributed learning-to-rank with integration of multiple frameworks including Dask, Spark, and PySpark. The interface is similar to the single-node counterpart. Please refer to document of the respective XGBoost interface for details. Scattering a query group onto multiple workers is theoretically sound but can affect the model accuracy. For most of the use cases, the small discrepancy is not an issue, as the amount of training data is usually large when distributed training is used. As a result, users don’t need to partition the data based on query groups. As long as each data partition is correctly sorted by query IDs, XGBoost can aggregate sample gradients accordingly.

**Reproducible Result**

Like any other tasks, XGBoost should generate reproducible results given the same hardware and software environments (and data partitions, if distributed interface is used). Even when the underlying environment has changed, the result should still be consistent. However, when the `lambdarank_pair_method` is set to mean, XGBoost uses random sampling, and results may differ depending on the platform used. The random number generator used on Windows (Microsoft Visual C++) is different from the ones used on other platforms like Linux (GCC, Clang), so the output varies significantly between these platforms.

**References**

---

1 `minstd_rand` implementation is different on MSVC. The implementations from GCC and Thrust produce the same output.
1.4.4 DART booster

XGBoost mostly combines a huge number of regression trees with a small learning rate. In this situation, trees added early are significant and trees added late are unimportant.

Vinayak and Gilad-Bachrach proposed a new method to add dropout techniques from the deep neural net community to boosted trees, and reported better results in some situations.

This is an instruction of new tree booster dart.

Original paper

Features

- Drop trees in order to solve the over-fitting.
  - Trivial trees (to correct trivial errors) may be prevented.

Because of the randomness introduced in the training, expect the following few differences:

- Training can be slower than gbtree because the random dropout prevents usage of the prediction buffer.
- The early stop might not be stable, due to the randomness.

How it works

- In \( m \)-th training round, suppose \( k \) trees are selected to be dropped.
- Let \( D = \sum_{i \in K} F_i \) be the leaf scores of dropped trees and \( F_m = \eta \tilde{F}_m \) be the leaf scores of a new tree.
- The objective function is as follows:

\[
\text{Obj} = \sum_{j=1}^{n} L \left( y_j, \hat{y}_j^{m-1} - D_j + \tilde{F}_m \right) + \Omega \left( \tilde{F}_m \right).
\]

- \( D \) and \( F_m \) are overshooting, so using scale factor

\[
\hat{y}_j^m = \sum_{i \notin K} F_i + a \left( \sum_{i \in K} F_i + bF_m \right).
\]

Parameters

The booster dart inherits gbtree booster, so it supports all parameters that gbtree does, such as eta, gamma, max_depth etc.

Additional parameters are noted below:

- sample_type: type of sampling algorithm.
  - uniform: (default) dropped trees are selected uniformly.
  - weighted: dropped trees are selected in proportion to weight.
- normalize_type: type of normalization algorithm.
– **tree**: (default) New trees have the same weight of each of dropped trees.

\[
a \left( \sum_{i \in K} F_i + \frac{1}{k} F_m \right) = a \left( \sum_{i \in K} F_i + \frac{\eta}{k} \tilde{F}_m \right) \\
\sim a \left( 1 + \frac{\eta}{k} \right) D \\
= \frac{k + \eta}{k} D = D, \\
a = \frac{k}{k + \eta}
\]

– **forest**: New trees have the same weight of sum of dropped trees (forest).

\[
a \left( \sum_{i \in K} F_i + F_m \right) = a \left( \sum_{i \in K} F_i + \eta \tilde{F}_m \right) \\
\sim a \left( 1 + \eta \right) D \\
= a(1 + \eta)D = D, \\
a = \frac{1}{1 + \eta}.
\]

- **rate_drop**: dropout rate.
  - range: [0.0, 1.0]
- **skip_drop**: probability of skipping dropout.
  - If a dropout is skipped, new trees are added in the same manner as gbtree.
  - range: [0.0, 1.0]

### Sample Script

```python
import xgboost as xgb

# read in data
dtrain = xgb.DMatrix('demo/data/agaricus.txt.train?format=libsvm')
dtest = xgb.DMatrix('demo/data/agaricus.txt.test?format=libsvm')

# specify parameters via map
param = {
    'booster': 'dart',
    'max_depth': 5, 'learning_rate': 0.1,
    'objective': 'binary:logistic',
    'sample_type': 'uniform',
    'normalize_type': 'tree',
    'rate_drop': 0.1,
    'skip_drop': 0.5
}

num_round = 50
bst = xgb.train(param, dtrain, num_round)
preds = bst.predict(dtest)
```
1.4.5 Monotonic Constraints

It is often the case in a modeling problem or project that the functional form of an acceptable model is constrained in some way. This may happen due to business considerations, or because of the type of scientific question being investigated. In some cases, where there is a very strong prior belief that the true relationship has some quality, constraints can be used to improve the predictive performance of the model.

A common type of constraint in this situation is that certain features bear a **monotonic** relationship to the predicted response:

\[
 f(x_1, x_2, \ldots, x_{n-1}, x_n) \leq f(x_1, x_2, \ldots, x', \ldots, x_{n-1}, x_n)
\]

whenever \( x \leq x' \) is an increasing constraint; or

\[
 f(x_1, x_2, \ldots, x_{n-1}, x_n) \geq f(x_1, x_2, \ldots, x', \ldots, x_{n-1}, x_n)
\]

whenever \( x \leq x' \) is a decreasing constraint.

XGBoost has the ability to enforce monotonicity constraints on any features used in a boosted model.

**A Simple Example**

To illustrate, let’s create some simulated data with two features and a response according to the following scheme

\[
 y = 5x_1 + \sin(10\pi x_1) - 5x_2 - \cos(10\pi x_2) + N(0, 0.01)x_1, x_2 \in [0, 1]
\]

The response generally increases with respect to the \( x_1 \) feature, but a sinusoidal variation has been superimposed, resulting in the true effect being non-monotonic. For the \( x_2 \) feature the variation is decreasing with a sinusoidal variation.

Let’s fit a boosted tree model to this data without imposing any monotonic constraints:
The black curves show the trend inferred from the model for each feature. To make these plots the distinguished feature \( x_i \) is fed to the model over a one-dimensional grid of values, while all the other features (in this case only one other feature) are set to their average values. We see that the model does a good job of capturing the general trend with the oscillatory wave superimposed.

Here is the same model, but fit with monotonicity constraints:

We see the effect of the constraint. For each variable the general direction of the trend is still evident, but the oscillatory behaviour no longer remains as it would violate our imposed constraints.

**Enforcing Monotonic Constraints in XGBoost**

It is very simple to enforce monotonicity constraints in XGBoost. Here we will give an example using Python, but the same general idea generalizes to other platforms.

Suppose the following code fits your model without monotonicity constraints

```python
model_no_constraints = xgb.train(params, dtrain,
                                  num_boost_round = 1000, evals = evallist,
                                  early_stopping_rounds = 10)
```
Then fitting with monotonicity constraints only requires adding a single parameter:

```python
params_constrained = params.copy()
params_constrained['monotone_constraints'] = (1, -1)
model_with_constraints = xgb.train(params_constrained, dtrain,
                                    num_boost_round = 1000,
                                    evals = evallist,
                                    early_stopping_rounds = 10)
```

In this example the training data \(X\) has two columns, and by using the parameter values \((1, -1)\) we are telling XGBoost to impose an increasing constraint on the first predictor and a decreasing constraint on the second.

Some other examples:

- \((1, 0)\): An increasing constraint on the first predictor and no constraint on the second.
- \((0, -1)\): No constraint on the first predictor and a decreasing constraint on the second.

**Note**

**Note for the ‘hist’ tree construction algorithm.** If `tree_method` is set to either `hist` or `approx`, enabling monotonic constraints may produce unnecessarily shallow trees. This is because the `hist` method reduces the number of candidate splits to be considered at each split. Monotonic constraints may wipe out all available split candidates, in which case no split is made. To reduce the effect, you may want to increase the `max_bin` parameter to consider more split candidates.

**Using feature names**

XGBoost’s Python and R packages support using feature names instead of feature indices for specifying the constraints. Given a data frame with columns \["f0", "f1", "f2"\], the monotonic constraint can be specified as \{"f0": 1, "f2": -1\} (Python) or as `list(f0=1, f2=-1)` (R, when using `xgboost()`, but not `xgb.train`), and "f1" will default to 0 (no constraint).

### 1.4.6 Feature Interaction Constraints

The decision tree is a powerful tool to discover interaction among independent variables (features). Variables that appear together in a traversal path are interacting with one another, since the condition of a child node is predicated on the condition of the parent node. For example, the highlighted red path in the diagram below contains three variables: \(x_1\), \(x_7\), and \(x_{10}\), so the highlighted prediction (at the highlighted leaf node) is the product of interaction between \(x_1\), \(x_7\), and \(x_{10}\).

When the tree depth is larger than one, many variables interact on the sole basis of minimizing training loss, and the resulting decision tree may capture a spurious relationship (noise) rather than a legitimate relationship that generalizes across different datasets. **Feature interaction constraints** allow users to decide which variables are allowed to interact and which are not.

Potential benefits include:

- Better predictive performance from focusing on interactions that work – whether through domain specific knowledge or algorithms that rank interactions
- Less noise in predictions; better generalization
• More control to the user on what the model can fit. For example, the user may want to exclude some interactions even if they perform well due to regulatory constraints.

A Simple Example

Feature interaction constraints are expressed in terms of groups of variables that are allowed to interact. For example, the constraint \([0, 1]\) indicates that variables \(x_0\) and \(x_1\) are allowed to interact with each other but with no other variable. Similarly, \([2, 3, 4]\) indicates that \(x_2, x_3,\) and \(x_4\) are allowed to interact with one another but with no other variable. A set of feature interaction constraints is expressed as a nested list, e.g. \([[[0, 1], [2, 3, 4]]\), where each inner list is a group of indices of features that are allowed to interact with each other.

In the following diagram, the left decision tree is in violation of the first constraint \([0, 1]\), whereas the right decision tree complies with both the first and second constraints \([0, 1], [2, 3, 4]\).

<table>
<thead>
<tr>
<th>forbidden</th>
<th>allowed</th>
</tr>
</thead>
</table>

Enforcing Feature Interaction Constraints in XGBoost

It is very simple to enforce feature interaction constraints in XGBoost. Here we will give an example using Python, but the same general idea generalizes to other platforms.

Suppose the following code fits your model without feature interaction constraints:

```python
model_no_constraints = xgb.train(params, dtrain,
                                 num_boost_round = 1000, evals = evallist,
                                 early_stopping_rounds = 10)
```

Then fitting with feature interaction constraints only requires adding a single parameter:

```python
params_constrained = params.copy()
# Use nested list to define feature interaction constraints
params_constrained['interaction_constraints'] = '[[0, 2], [1, 3, 4], [5, 6]]'
# Features 0 and 2 are allowed to interact with each other but with no other feature
# Features 1, 3, 4 are allowed to interact with one another but with no other feature
# Features 5 and 6 are allowed to interact with each other but with no other feature
model_with_constraints = xgb.train(params_constrained, dtrain,
                                    num_boost_round = 1000, evals = evallist,
                                    early_stopping_rounds = 10)
```

Using feature name instead

XGBoost’s Python and R packages support using feature names instead of feature index for specifying the constraints. Given a data frame with columns \["f0", "f1", "f2"]\, the feature interaction constraint can be specified as \[[["f0", "f2"]\) (Python) or \texttt{list(c("f0", "f2"))} (R, when passing them to function \texttt{xgboost()}).
The intuition behind interaction constraints is simple. Users may have prior knowledge about relations between different features, and encode it as constraints during model construction. But there are also some subtleties around specifying constraints. Take the constraint \([1, 2], [2, 3, 4]\) as an example. The second feature appears in two different interaction sets, \([1, 2]\) and \([2, 3, 4]\). So the union set of features allowed to interact with 2 is \(\{1, 3, 4\}\). In the following diagram, the root splits at feature 2. Because all its descendants should be able to interact with it, all 4 features are legitimate split candidates at the second layer. At first sight, this might look like disregarding the specified constraint sets, but it is not.

![Diagram of feature interaction](image)

Fig. 1: \(\{1, 2, 3, 4\}\) represents the sets of legitimate split features.

This has lead to some interesting implications of feature interaction constraints. Take \([\emptyset, 1], [\emptyset, 1, 2], [1, 2]\) as another example. Assuming we have only 3 available features in our training datasets for presentation purpose, careful readers might have found out that the above constraint is the same as simply \([\emptyset, 1, 2]\). Since no matter which feature is chosen for split in the root node, all its descendants are allowed to include every feature as legitimate split candidates without violating interaction constraints.

For one last example, we use \([\emptyset, 1], [1, 3, 4]\) and choose feature 0 as split for the root node. At the second layer of the built tree, 1 is the only legitimate split candidate except for 0 itself, since they belong to the same constraint set. Following the grow path of our example tree below, the node at the second layer splits at feature 1. But due to the fact that 1 also belongs to second constraint set \([1, 3, 4]\), at the third layer, we are allowed to include all features as split candidates and still comply with the interaction constraints of its ascendants.

### 1.4.7 Survival Analysis with Accelerated Failure Time

- What is survival analysis?
- Accelerated Failure Time model
- How to use

---

1.4. XGBoost Tutorials 55
What is survival analysis?

Survival analysis (regression) models time to an event of interest. Survival analysis is a special kind of regression and differs from the conventional regression task as follows:

- The label is always positive, since you cannot wait a negative amount of time until the event occurs.
- The label may not be fully known, or censored, because “it takes time to measure time.”

The second bullet point is crucial and we should dwell on it more. As you may have guessed from the name, one of the earliest applications of survival analysis is to model mortality of a given population. Let’s take NCCTG Lung Cancer Dataset as an example. The first 8 columns represent features and the last column, Time to death, represents the label.

<table>

</tr>
</tbody>
</table>

Take a close look at the label for the third patient. His label is a range, not a single number. The third patient’s label is said to be censored, because for some reason the experimenters could not get a complete measurement for that label. One possible scenario: the patient survived the first 1010 days and walked out of the clinic on the 1011th day, so his death was not directly observed. Another possibility: The experiment was cut short (since you cannot run it forever) before his death could be observed. In any case, his label is [1010, +∞), meaning his time to death can be any number that’s higher than 1010, e.g. 2000, 3000, or 10000.
There are four kinds of censoring:

- **Uncensored**: the label is not censored and given as a single number.
- **Right-censored**: the label is of form \([a, +\infty)\), where \(a\) is the lower bound.
- **Left-censored**: the label is of form \([0, b]\), where \(b\) is the upper bound.
- **Interval-censored**: the label is of form \([a, b]\), where \(a\) and \(b\) are the lower and upper bounds, respectively.

Right-censoring is the most commonly used.

### Accelerated Failure Time model

**Accelerated Failure Time (AFT)** model is one of the most commonly used models in survival analysis. The model is of the following form:

\[
\ln Y = \langle w, x \rangle + \sigma Z
\]

where

- \(x\) is a vector in \(\mathbb{R}^d\) representing the features.
- \(w\) is a vector consisting of \(d\) coefficients, each corresponding to a feature.
- \(\langle \cdot, \cdot \rangle\) is the usual dot product in \(\mathbb{R}^d\).
- \(\ln (\cdot)\) is the natural logarithm.
- \(Y\) and \(Z\) are random variables.
  - \(Y\) is the output label.
  - \(Z\) is a random variable of a known probability distribution. Common choices are the normal distribution, the logistic distribution, and the extreme distribution. Intuitively, \(Z\) represents the “noise” that pulls the prediction \(\langle w, x \rangle\) away from the true log label \(\ln Y\).
- \(\sigma\) is a parameter that scales the size of \(Z\).

Note that this model is a generalized form of a linear regression model \(Y = \langle w, x \rangle\). In order to make AFT work with gradient boosting, we revise the model as follows:

\[
\ln Y = T(x) + \sigma Z
\]

where \(T(x)\) represents the output from a decision tree ensemble, given input \(x\). Since \(Z\) is a random variable, we have a likelihood defined for the expression \(\ln Y = T(x) + \sigma Z\). So the goal for XGBoost is to maximize the (log) likelihood by fitting a good tree ensemble \(T(x)\).

### How to use

The first step is to express the labels in the form of a range, so that **every data point has two numbers associated with it, namely the lower and upper bounds for the label**. For uncensored labels, use a degenerate interval of form \([a, a]\).

<table>
<thead>
<tr>
<th>Censoring type</th>
<th>Interval form</th>
<th>Lower bound finite?</th>
<th>Upper bound finite?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uncensored</td>
<td>([a, a])</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Right-censored</td>
<td>([a, +\infty))</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Left-censored</td>
<td>([0, b])</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Interval-censored</td>
<td>([a, b])</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>
Collect the lower bound numbers in one array (let’s call it `y_lower_bound`) and the upper bound number in another array (call it `y_upper_bound`). The ranged labels are associated with a data matrix object via calls to `xgboost.DMatrix.set_float_info()`:

```python
# 4-by-2 Data matrix
X = np.array([[1, -1], [-1, 1], [0, 1], [1, 0]])
dtrain = xgb.DMatrix(X)

# Associate ranged labels with the data matrix.
# This example shows each kind of censored labels.
# uncensored right left interval
y_lower_bound = np.array([2.0, 3.0, 0.0, 4.0])
y_upper_bound = np.array([2.0, +np.inf, 4.0, 5.0])
dtrain.set_float_info('label_lower_bound', y_lower_bound)
dtrain.set_float_info('label_upper_bound', y_upper_bound)
```

```r
library(xgboost)

# 4-by-2 Data matrix
X <- matrix(c(1., -1., -1., 1., 0., 1., 1., 0.),
            nrow=4, ncol=2, byrow=TRUE)
dtrain <- xgb.DMatrix(X)

# Associate ranged labels with the data matrix.
# This example shows each kind of censored labels.
# uncensored right left interval
y_lower_bound <- c(2., 3., 0., 4.)
y_upper_bound <- c(2., +Inf, 4., 5.)
setinfo(dtrain, 'label_lower_bound', y_lower_bound)
setinfo(dtrain, 'label_upper_bound', y_upper_bound)
```

Now we are ready to invoke the training API:

```python
params = {
    'objective': 'survival:aft',
    'eval_metric': 'aft-nloglik',
    'aft_loss_distribution': 'normal',
    'aft_loss_distribution_scale': 1.20,
    'tree_method': 'hist',
    'learning_rate': 0.05,
    'max_depth': 2
}
bst = xgb.train(params, dtrain, num_boost_round=5,
               evals=[(dtrain, 'train')])
```

```r
params <- list(objective='survival:aft',
               eval_metric='aft-nloglik',
               (continues on next page)```
We set the objective parameter to `survival:aft` and `eval_metric` to `aft-nloglik`, so that the log likelihood for the AFT model would be maximized. (XGBoost will actually minimize the negative log likelihood, hence the name `aft-nloglik`.)

The parameter `aft_loss_distribution` corresponds to the distribution of the $Z$ term in the AFT model, and `aft_loss_distribution_scale` corresponds to the scaling factor $\sigma$.

Currently, you can choose from three probability distributions for `aft_loss_distribution`:

<table>
<thead>
<tr>
<th>aft_loss_distribution</th>
<th>Probability Density Function (PDF)</th>
</tr>
</thead>
<tbody>
<tr>
<td>normal</td>
<td>$\frac{\exp(-z^2/2)}{\sqrt{2\pi}}$</td>
</tr>
<tr>
<td>logistic</td>
<td>$\frac{(1 + e^z)^2}{e^z e^{-\exp z}}$</td>
</tr>
<tr>
<td>extreme</td>
<td>$e^z e^{-\exp z}$</td>
</tr>
</tbody>
</table>

Note that it is not yet possible to set the ranged label using the scikit-learn interface (e.g. `xgboost.XGBRegressor`). For now, you should use `xgboost.train` with `xgboost.DMatrix`. For a collection of Python examples, see *Survival Analysis Walkthrough*.

### 1.4.8 Categorical Data

As of XGBoost 1.6, the feature is experimental and has limited features. Only the Python package is fully supported.

Starting from version 1.5, the XGBoost Python package has experimental support for categorical data available for public testing. For numerical data, the split condition is defined as `value < threshold`, while for categorical data the split is defined depending on whether partitioning or onehot encoding is used. For partition-based splits, the splits are specified as `value \in categories`, where `categories` is the set of categories in one feature. If onehot encoding is used instead, then the split is defined as `value == category`. More advanced categorical split strategy is planned for future releases and this tutorial details how to inform XGBoost about the data type.
Training with scikit-learn Interface

The easiest way to pass categorical data into XGBoost is using dataframe and the scikit-learn interface like XGBClassifier. For preparing the data, users need to specify the data type of input predictor as category. For pandas/cudf Dataframe, this can be achieved by

\[
\text{X["cat_feature"].astype("category")}
\]

for all columns that represent categorical features. After which, users can tell XGBoost to enable training with categorical data. Assuming that you are using the XGBClassifier for classification problem, specify the parameter enable_categorical:

```python
# Supported tree methods are 'approx' and 'hist'.
clf = xgb.XGBClassifier(tree_method="hist", enable_categorical=True, device="cuda")
# X is the dataframe we created in previous snippet
clf.fit(X, y)
# Must use JSON/UBJSON for serialization, otherwise the information is lost.
clf.save_model("categorical-model.json")
```

Once training is finished, most of other features can utilize the model. For instance one can plot the model and calculate the global feature importance:

```python
# Get a graph
graph = xgb.to_graphviz(clf, num_trees=1)
# Or get a matplotlib axis
ax = xgb.plot_tree(clf, num_trees=1)
# Get feature importances
clf.feature_importances_
```

The scikit-learn interface from dask is similar to single node version. The basic idea is create dataframe with category feature type, and tell XGBoost to use it by setting the enable_categorical parameter. See Getting started with categorical data for a worked example of using categorical data with scikit-learn interface with one-hot encoding. A comparison between using one-hot encoded data and XGBoost’s categorical data support can be found Train XGBoost with cat_in_the_dat dataset.

Optimal Partitioning

Added in version 1.6.

Optimal partitioning is a technique for partitioning the categorical predictors for each node split, the proof of optimality for numerical output was first introduced by [1]. The algorithm is used in decision trees [2], later LightGBM [3] brought it to the context of gradient boosting trees and now is also adopted in XGBoost as an optional feature for handling categorical splits. More specifically, the proof by Fisher [1] states that, when trying to partition a set of discrete values into groups based on the distances between a measure of these values, one only needs to look at sorted partitions instead of enumerating all possible permutations. In the context of decision trees, the discrete values are categories, and the measure is the output leaf value. Intuitively, we want to group the categories that output similar leaf values. During split finding, we first sort the gradient histogram to prepare the contiguous partitions then enumerate the splits according to these sorted values. One of the related parameters for XGBoost is max_cat_to_onehot, which controls whether one-hot encoding or partitioning should be used for each feature, see Parameters for Categorical Feature for details.
Using native interface

The scikit-learn interface is user friendly, but lacks some features that are only available in native interface. For instance users cannot compute SHAP value directly. Also native interface supports more data types. To use the native interface with categorical data, we need to pass the similar parameter to `DMatrix` or `QuantileDMatrix` and the `train` function. For dataframe input:

```python
# X is a dataframe we created in previous snippet
Xy = xgb.DMatrix(X, y, enable_categorical=True)
booster = xgb.train({'tree_method': 'hist', 'max_cat_to_onehot': 5}, Xy)
# Must use JSON for serialization, otherwise the information is lost
booster.save_model("categorical-model.json")
```

SHAP value computation:

```python
SHAP = booster.predict(Xy, pred_interactions=True)
# categorical features are listed as "c"
print(booster.feature_types)
```

For other types of input, like `numpy` array, we can tell XGBoost about the feature types by using the `feature_types` parameter in `DMatrix`:

```python
# "q" is numerical feature, while "c" is categorical feature
ft = ['q', 'c', 'c']
X: np.ndarray = load_my_data()
assert X.shape[1] == 3
Xy = xgb.DMatrix(X, y, feature_types=ft, enable_categorical=True)
```

For numerical data, the feature type can be "q" or "float", while for categorical feature it's specified as "c". The Dask module in XGBoost has the same interface so `dask.Array` can also be used for categorical data. Lastly, the sklearn interface `XGBRegressor` has the same parameter.

Data Consistency

XGBoost accepts parameters to indicate which feature is considered categorical, either through the `dtypes` of a dataframe or through the `feature_types` parameter. However, XGBoost by itself doesn't store information on how categories are encoded in the first place. For instance, given an encoding schema that maps music genres to integer codes:

```json
{"acoustic": 0, "indie": 1, "blues": 2, "country": 3}
```

XGBoost doesn't know this mapping from the input and hence cannot store it in the model. The mapping usually happens in the users' data engineering pipeline with column transformers like `sklearn.preprocessing.OrdinalEncoder`. To make sure correct result from XGBoost, users need to keep the pipeline for transforming data consistent across training and testing data. One should watch out for errors like:

```python
X_train["genre"] = X_train["genre"].astype("category")
reg = xgb.XGBRegressor(enable_categorical=True).fit(X_train, y_train)

# invalid encoding
X_test["genre"] = X_test["genre"].astype("category")
reg.predict(X_test)
```
In the above snippet, training data and test data are encoded separately, resulting in two different encoding schemas and invalid prediction result. See Feature engineering pipeline for categorical data for a worked example using ordinal encoder.

**Miscellaneous**

By default, XGBoost assumes input categories are integers starting from 0 till the number of categories \([0, n_{\text{categories}}]\). However, user might provide inputs with invalid values due to mistakes or missing values in training dataset. It can be negative value, integer values that can not be accurately represented by 32-bit floating point, or values that are larger than actual number of unique categories. During training this is validated but for prediction it’s treated as the same as not-chosen category for performance reasons.

**References**

1.4.9 Multiple Outputs

Added in version 1.6.

Starting from version 1.6, XGBoost has experimental support for multi-output regression and multi-label classification with Python package. Multi-label classification usually refers to targets that have multiple non-exclusive class labels. For instance, a movie can be simultaneously classified as both sci-fi and comedy. For detailed explanation of terminologies related to different multi-output models please refer to the scikit-learn user guide.

**Note**

As of XGBoost 2.0, the feature is experimental and has limited features. Only the Python package is tested.

**Training with One-Model-Per-Target**

By default, XGBoost builds one model for each target similar to sklearn meta estimators, with the added benefit of reusing data and other integrated features like SHAP. For a worked example of regression, see A demo for multi-output regression. For multi-label classification, the binary relevance strategy is used. Input \(y\) should be of shape \((n_{\text{samples}}, n_{\text{classes}})\) with each column having a value of 0 or 1 to specify whether the sample is labeled as positive for respective class. Given a sample with 3 output classes and 2 labels, the corresponding \(y\) should be encoded as \([1, 0, 1]\) with the second class labeled as negative and the rest labeled as positive. At the moment XGBoost supports only dense matrix for labels.

```python
from sklearn.datasets import make_multilabel_classification
import numpy as np

X, y = make_multilabel_classification()
```
The feature is still under development with limited support from objectives and metrics.

**Training with Vector Leaf**

Added in version 2.0.

**Note**

This is still working-in-progress, and most features are missing.

XGBoost can optionally build multi-output trees with the size of leaf equals to the number of targets when the tree method *hist* is used. The behavior can be controlled by the `multi_strategy` training parameter, which can take the value *one_output_per_tree* (the default) for building one model per-target or *multi_output_tree* for building multi-output trees.

```
clf = xgb.XGBClassifier(tree_method="hist", multi_strategy="multi_output_tree")
```

See [A demo for multi-output regression](#) for a worked example with regression.

### 1.4.10 Random Forests(TM) in XGBoost

XGBoost is normally used to train gradient-boosted decision trees and other gradient boosted models. Random Forests use the same model representation and inference, as gradient-boosted decision trees, but a different training algorithm. One can use XGBoost to train a standalone random forest or use random forest as a base model for gradient boosting. Here we focus on training standalone random forest.

We have native APIs for training random forests since the early days, and a new Scikit-Learn wrapper after 0.82 (not included in 0.82). Please note that the new Scikit-Learn wrapper is still **experimental**, which means we might change the interface whenever needed.

**Standalone Random Forest With XGBoost API**

The following parameters must be set to enable random forest training.

- `booster` should be set to `gbtree`, as we are training forests. Note that as this is the default, this parameter needn’t be set explicitly.
- `subsample` must be set to a value less than 1 to enable random selection of training cases (rows).
- One of `colsample_by*` parameters must be set to a value less than 1 to enable random selection of columns. Normally, `colsample_bytree` would be set to a value less than 1 to randomly sample columns at each tree split.
- `num_parallel_tree` should be set to the size of the forest being trained.
- `num_boost_round` should be set to 1 to prevent XGBoost from boosting multiple random forests. Note that this is a keyword argument to `train()`, and is not part of the parameter dictionary.
xgboost, Release 2.1.1

• **eta** (alias: **learning_rate**) must be set to 1 when training random forest regression.

• **random_state** can be used to seed the random number generator.

Other parameters should be set in a similar way they are set for gradient boosting. For instance, **objective** will typically be `reg:squarederror` for regression and `binary:logistic` for classification, **lambda** should be set according to a desired regularization weight, etc.

If both `num_parallel_tree` and `num_boost_round` are greater than 1, training will use a combination of random forest and gradient boosting strategy. It will perform `num_boost_round` rounds, boosting a random forest of `num_parallel_tree` trees at each round. If early stopping is not enabled, the final model will consist of `num_parallel_tree * num_boost_round` trees.

Here is a sample parameter dictionary for training a random forest on a GPU using xgboost:

```python
params = {
    "colsample_bynode": 0.8,
    "learning_rate": 1,
    "max_depth": 5,
    "num_parallel_tree": 100,
    "objective": "binary:logistic",
    "subsample": 0.8,
    "tree_method": "hist",
    "device": "cuda",
}
```

A random forest model can then be trained as follows:

```python
bst = train(params, dmatrix, num_boost_round=1)
```

### Standalone Random Forest With Scikit-Learn-Like API

`XGBRFClassifier` and `XGBRFRegressor` are SKL-like classes that provide random forest functionality. They are basically versions of `XGBClassifier` and `XGBRegressor` that train random forest instead of gradient boosting, and have default values and meaning of some of the parameters adjusted accordingly. In particular:

- **n_estimators** specifies the size of the forest to be trained; it is converted to `num_parallel_tree`, instead of the number of boosting rounds
- **learning_rate** is set to 1 by default
- **colsample_bynode** and **subsample** are set to 0.8 by default
- **booster** is always `gbtree`

For a simple example, you can train a random forest regressor with:

```python
from sklearn.model_selection import KFold

# Your code ...

kf = KFold(n_splits=2)
for train_index, test_index in kf.split(X, y):
    xgb_model = xgb.XGBRFRegressor(random_state=42).fit(
        X[train_index], y[train_index])
```

Note that these classes have a smaller selection of parameters compared to using `train()`. In particular, it is impossible to combine random forests with gradient boosting using this API.
Caveats

- XGBoost uses 2nd order approximation to the objective function. This can lead to results that differ from a random forest implementation that uses the exact value of the objective function.
- XGBoost does not perform replacement when subsampling training cases. Each training case can occur in a subsampled set either 0 or 1 time.

1.4.11 Distributed XGBoost on Kubernetes

Distributed XGBoost training and batch prediction on Kubernetes are supported via Kubeflow XGBoost Training Operator.

Instructions

In order to run a XGBoost job in a Kubernetes cluster, perform the following steps:

1. Install XGBoost Operator on the Kubernetes cluster.
   a. XGBoost Operator is designed to manage the scheduling and monitoring of XGBoost jobs. Follow this installation guide to install XGBoost Operator.

2. Write application code that will be executed by the XGBoost Operator.
   a. To use XGBoost Operator, you’ll have to write a couple of Python scripts that implement the distributed training logic for XGBoost. Please refer to the Iris classification example.
   b. Data reader/writer: you need to implement the data reader and writer based on the specific requirements of your chosen data source. For example, if your dataset is stored in a Hive table, you have to write the code to read from or write to the Hive table based on the index of the worker.
   c. Model persistence: in the Iris classification example, the model is stored in Alibaba OSS. If you want to store your model in other storages such as Amazon S3 or Google NFS, you’ll need to implement the model persistence logic based on the requirements of the chosen storage system.

3. Configure the XGBoost job using a YAML file.
   a. YAML file is used to configure the computational resources and environment for your XGBoost job to run, e.g. the number of workers/masters and the number of CPU/GPUs. Please refer to this YAML template for an example.

4. Submit XGBoost job to a Kubernetes cluster.
   a. Use kubectl to submit a distributed XGBoost job as illustrated here.

Support

Please submit an issue on XGBoost Operator repo for any feature requests or problems.
1.4.12 Distributed XGBoost with Dask

Dask is a parallel computing library built on Python. Dask allows easy management of distributed workers and excels at handling large distributed data science workflows. The implementation in XGBoost originates from dask-xgboost with some extended functionalities and a different interface. The tutorial here focuses on basic usage of dask with CPU tree algorithms. For an overview of GPU based training and internal workings, see A New, Official Dask API for XGBoost.

• Why is the initialization of DaskDMatrix so slow and throws weird errors
• Reproducible Result
• Memory Usage

Requirements

Dask can be installed using either pip or conda (see the dask installation documentation for more information). For accelerating XGBoost with GPUs, dask-cuda is recommended for creating GPU clusters.

Overview

A dask cluster consists of three different components: a centralized scheduler, one or more workers, and one or more clients which act as the user-facing entry point for submitting tasks to the cluster. When using XGBoost with dask, one needs to call the XGBoost dask interface from the client side. Below is a small example which illustrates basic usage of running XGBoost on a dask cluster:

```python
from xgboost import dask as dxgb
import dask.array as da
```
```python
import dask.distributed

if __name__ == "__main__":
    cluster = dask.distributed.LocalCluster()
    client = dask.distributed.Client(cluster)

    # X and y must be Dask dataframes or arrays
    num_obs = 1e5
    num_features = 20
    X = da.random.random(size=(num_obs, num_features), chunks=(1000, num_features))
    y = da.random.random(size=(num_obs, 1), chunks=(1000, 1))

    dtrain = dxgb.DaskDMatrix(client, X, y)
    # or
    # dtrain = dxgb.DaskQuantileDMatrix(client, X, y)

    output = dxgb.train(
        client,
        {
            "verbosity": 2, "tree_method": "hist", "objective": "reg:squarederror"},
        dtrain,
        num_boost_round=4,
        evals=[[dtrain, "train"]],
    )
```

Here we first create a cluster in single-node mode with `dask.distributed.LocalCluster`, then connect a `dask.distributed.Client` to this cluster, setting up an environment for later computation. Notice that the cluster construction is guarded by `__name__ == "__main__"`, which is necessary otherwise there might be obscure errors.

We then create a `xgboost.dask.DaskDMatrix` object and pass it to `xgboost.dask.train()`, along with some other parameters, much like XGBoost’s normal, non-dask interface. Unlike that interface, data and label must be either Dask DataFrame or Dask Array instances.

The primary difference with XGBoost’s dask interface is we pass our dask client as an additional argument for carrying out the computation. Note that if client is set to `None`, XGBoost will use the default client returned by dask.

There are two sets of APIs implemented in XGBoost. The first set is functional API illustrated in above example. Given the data and a set of parameters, the `train` function returns a model and the computation history as a Python dictionary:

```python
{
    "booster": Booster,
    "history": dict,
}
```

For prediction, pass the output returned by `train` into `xgboost.dask.predict()`:

```python
prediction = dxgb.predict(client, output, dtrain)
# Or equivalently, pass `output['booster']`:
prediction = dxgb.predict(client, output['booster'], dtrain)
```

Eliminating the construction of DaskDMatrix is also possible, this can make the computation a bit faster when meta information like `base_margin` is not needed:
Here prediction is a dask Array object containing predictions from model if input is a DaskDMatrix or da.Array. When putting dask collection directly into the predict function or using xgboost.dask.inplace_predict(), the output type depends on input data. See next section for details.

Alternatively, XGBoost also implements the Scikit-Learn interface with DaskXGBClassifier, DaskXGBRegressor, DaskXGBRanker and 2 random forest variances. This wrapper is similar to the single node Scikit-Learn interface in xgboost, with dask collection as inputs and has an additional client attribute. See following sections and XGBoost Dask Feature Walkthrough for more examples.

### Running prediction

In previous example we used DaskDMatrix as input to predict function. In practice, it’s also possible to call predict function directly on dask collections like Array and DataFrame and might have better prediction performance. When DataFrame is used as prediction input, the result is a dask Series instead of array. Also, there’s in-place predict support on dask interface, which can help reducing both memory usage and prediction time.

```python
# dtrain is the DaskDMatrix defined above.
prediction = dxgb.predict(client, booster, dtrain)
```

or equivalently:

```python
# where X is a dask DataFrame or dask Array.
prediction = dxgb.predict(client, booster, X)
```

Also for inplace prediction:

```python
# where X is a dask DataFrame or dask Array backed by cupy or cuDF.
booster.set_param({'device': 'cuda'})
prediction = dxgb.inplace_predict(client, booster, X)
```

When input is da.Array object, output is always da.Array. However, if the input type is dd.DataFrame, output can be dd.Series, dd.DataFrame or da.Array, depending on output shape. For example, when SHAP-based prediction is used, the return value can have 3 or 4 dimensions, in such cases an Array is always returned.

The performance of running prediction, either using predict or inplace_predict, is sensitive to number of blocks. Internally, it’s implemented using da.map_blocks and dd.map_partitions. When number of partitions is large and each of them have only small amount of data, the overhead of calling predict becomes visible. On the other hand, if not using GPU, the number of threads used for prediction on each block matters. Right now, xgboost uses single thread for each partition. If the number of blocks on each workers is smaller than number of cores, then the CPU workers might not be fully utilized.

One simple optimization for running consecutive predictions is using distributed.Future:

```python
dataset = [X_0, X_1, X_2]
booster_f = client.scatter(booster, broadcast=True)
futures = []
for X in dataset:
    # Here we pass in a future instead of concrete booster
    shap_f = dxgb.predict(client, booster_f, X, pred_contribs=True)
    futures.append(shap_f)
```
results = client.gather(futures)

This is only available on functional interface, as the Scikit-Learn wrapper doesn’t know how to maintain a valid future for booster. To obtain the booster object from Scikit-Learn wrapper object:

```python
cls = dxgb.DaskXGBClassifier()
cls.fit(X, y)

booster = cls.get_booster()
```

### Scikit-Learn Estimator Interface

As mentioned previously, there’s another interface that mimics the scikit-learn estimators with higher level of abstraction. The interface is easier to use compared to the functional interface but with more constraints. It’s worth mentioning that, although the interface mimics scikit-learn estimators, it doesn’t work with normal scikit-learn utilities like GridSearchCV as scikit-learn doesn’t understand distributed dask data collection.

```python
from distributed import LocalCluster, Client
from xgboost import dask as dxgb

def main(client: Client) -> None:
    X, y = load_data()
    clf = dxgb.DaskXGBClassifier(n_estimators=100, tree_method="hist")
    clf.client = client  # assign the client
    clf.fit(X, y, eval_set=[(X, y)])
    proba = clf.predict_proba(X)

if __name__ == "__main__":
    with LocalCluster() as cluster:
        with Client(cluster) as client:
            main(client)
```
GPU acceleration

For most of the use cases with GPUs, the Dask-CUDA project should be used to create the cluster, which automatically configures the correct device ordinal for worker processes. As a result, users should NOT specify the ordinal (good: device=cuda, bad: device=cuda:1). See Example of training with Dask on GPU and Use scikit-learn regressor interface with GPU histogram tree method for worked examples.

Working with other clusters

Using Dask’s LocalCluster is convenient for getting started quickly on a local machine. Once you’re ready to scale your work, though, there are a number of ways to deploy Dask on a distributed cluster. You can use Dask-CUDA, for example, for GPUs and you can use Dask Cloud Provider to deploy Dask clusters in the cloud. See the Dask documentation for a more comprehensive list.

In the example below, a KubeCluster is used for deploying Dask on Kubernetes:

```python
from dask_kubernetes.operator import KubeCluster  # Need to install the ``dask-kubernetes`` package
from dask_kubernetes.operator.kubecluster.kubecluster import CreateMode

from dask.distributed import Client
from xgboost import dask as dxgb
import dask.array as da

def main():
    """Connect to a remote kube cluster with GPU nodes and run training on it.""
    m = 1000
    n = 10
    kWorkers = 2  # assuming you have 2 GPU nodes on that cluster.
    # You need to work out the worker-spec yourself. See document in dask_kubernetes for
    # its usage. Here we just want to show that XGBoost works on various clusters.

    # See notes below for why we use pre-allocated cluster.
    with KubeCluster(
        name="xgboost-test",
        image="my-image-name:latest",
        n_workers=kWorkers,
        create_mode=CreateMode.CONNECT_ONLY,
        shutdown_on_close=False,
    ) as cluster:
        with Client(cluster) as client:
            X = da.random.random(size=(m, n), chunks=100)
            y = X.sum(axis=1)

            regressor = dxgb.DaskXGBRegressor(n_estimators=10, missing=0.0)
            regressor.client = client
            regressor.set_params(tree_method='hist', device="cuda")
            regressor.fit(X, y, eval_set=[(X, y)])

if __name__ == '__main__':
    # Launch the kube cluster on somewhere like GKE, then run this as client process.
```
(continues on next page)
Different cluster classes might have subtle differences like network configuration, or specific cluster implementation might contain bugs that we are not aware of. Open an issue if such case is found and there’s no documentation on how to resolve it in that cluster implementation.

An interesting aspect of the Kubernetes cluster is that the pods may become available after the Dask workflow has begun, which can cause issues with distributed XGBoost since XGBoost expects the nodes used by input data to remain unchanged during training. To use Kubernetes clusters, it is necessary to wait for all the pods to be online before submitting XGBoost tasks. One can either create a wait function in Python or simply pre-allocate a cluster with k8s tools (like kubectl) before running dask workflows. To pre-allocate a cluster, we can first generate the cluster spec using dask kubernetes:

```python
import json

from dask_kubernetes.operator import make_cluster_spec

spec = make_cluster_spec(name="xgboost-test", image="my-image-name:latest", n_workers=16)
with open("cluster-spec.json", "w") as fd:
    json.dump(spec, fd, indent=2)

kubectl apply -f ./cluster-spec.json
```

Check whether the pods are available:

```
kubectl get pods
```

Once all pods have been initialized, the Dask XGBoost workflow can be run, as in the previous example. It is important to ensure that the cluster sets the parameter `create_mode=CreateMode.CONNECT_ONLY` and optionally `shutdown_on_close=False` if you do not want to shut down the cluster after a single job.

### Threads

XGBoost has built in support for parallel computation through threads by the setting `nthread` parameter (n_jobs for scikit-learn). If these parameters are set, they will override the configuration in Dask. For example:

```python
with dask.distributed.LocalCluster(n_workers=7, threads_per_worker=4) as cluster:
```

There are 4 threads allocated for each dask worker. Then by default XGBoost will use 4 threads in each process for training. But if `nthread` parameter is set:

```python
output = dxgb.train(
    client,
    "{"verbosity": 1, "nthread": 8, "tree_method": "hist"},
    dtrain,
    num_boost_round=4,
    evals=[(dtrain, "train")],
)
```

XGBoost will use 8 threads in each training process.
Working with asyncio

Added in version 1.2.0.

XGBoost’s dask interface supports the new asyncio in Python and can be integrated into asynchronous workflows. For using dask with asynchronous operations, please refer to this dask example and document in distributed. To use XGBoost’s dask interface asynchronously, the client which is passed as an argument for training and prediction must be operating in asynchronous mode by specifying asynchronous=True when the client is created (example below). All functions (including DaskDMatrix) provided by the functional interface will then return coroutines which can then be awaited to retrieve their result.

Functional interface:

```python
async with dask.distributed.Client(scheduler_address, asynchronous=True) as client:
    X, y = generate_array()
    m = await dxgb.DaskDMatrix(client, X, y)
    output = await dxgb.train(client, {}, dtrain=m)

    with_m = await dxgb.predict(client, output, m)
    with_X = await dxgb.predict(client, output, X)
    inplace = await dxgb.inplace_predict(client, output, X)

    # Use `client.compute` instead of the `compute` method from dask collection
    print(await client.compute(with_m))
```

While for the Scikit-Learn interface, trivial methods like set_params and accessing class attributes like evals_result() do not require await. Other methods involving actual computation will return a coroutine and hence require awaiting:

```python
async with dask.distributed.Client(scheduler_address, asynchronous=True) as client:
    X, y = generate_array()
    regressor = await dxgb.DaskXGBRegressor(verbosity=1, n_estimators=2)
    regressor.set_params(tree_method='hist')  # trivial method, synchronous operation
    regressor.client = client  # accessing attribute, synchronous operation
    regressor = await regressor.fit(X, y, eval_set=[(X, y)])
    prediction = await regressor.predict(X)

    # Use `client.compute` instead of the `compute` method from dask collection
    print(await client.compute(prediction))
```

Evaluation and Early Stopping

Added in version 1.3.0.

The Dask interface allows the use of validation sets that are stored in distributed collections (Dask DataFrame or Dask Array). These can be used for evaluation and early stopping.

To enable early stopping, pass one or more validation sets containing DaskDMatrix objects.

```python
import dask.array as da
from xgboost import dask as dxgb

num_rows = 1e6
num_features = 100
num_partitions = 10
```
rows_per_chunk = num_rows / num_partitions

data = da.random.random(
    size=(num_rows, num_features),
    chunks=(rows_per_chunk, num_features)
)

labels = da.random.random(
    size=(num_rows, 1),
    chunks=(rows_per_chunk, 1)
)

X_eval = da.random.random(
    size=(num_rows, num_features),
    chunks=(rows_per_chunk, num_features)
)

y_eval = da.random.random(
    size=(num_rows, 1),
    chunks=(rows_per_chunk, 1)
)

dtrain = dxgb.DaskDMatrix(
    client=client,
    data=data,
    label=labels
)

dvalid = dxgb.DaskDMatrix(
    client=client,
    data=X_eval,
    label=y_eval
)

result = dxgb.train(
    client=client,
    params={
        "objective": "reg:squarederror",
    },
    dtrain=dtrain,
    num_boost_round=10,
    evals=[(dvalid, "valid1")],
    early_stopping_rounds=3
)

When validation sets are provided to `xgboost.dask.train()` in this way, the model object returned by `xgboost.dask.train()` contains a history of evaluation metrics for each validation set, across all boosting rounds.

```python
print(result["history"])
# {"valid1": OrderedDict([('rmse', [0.28857, 0.28858, 0.288592, 0.288598])])}
```

If early stopping is enabled by also passing `early_stopping_rounds`, you can check the best iteration in the returned booster.
booster = result["booster"]
print(booster.best_iteration)
best_model = booster[: booster.best_iteration]

Other customization

XGBoost dask interface accepts other advanced features found in single node Python interface, including callback functions, custom evaluation metric and objective:

```python
def eval_error_metric(predt, dtrain: xgb.DMatrix):
    label = dtrain.get_label()
    r = np.zeros(predt.shape)
    gt = predt > 0.5
    r[gt] = 1 - label[gt]
    le = predt <= 0.5
    r[le] = label[le]
    return 'CustomErr', np.sum(r)

# custom callback
early_stop = xgb.callback.EarlyStopping(
    rounds=early_stopping_rounds,
    metric_name="CustomErr",
    data_name="Train",
    save_best=True,
)

booster = dxgb.train(
    client,
    params={
        "objective": "binary:logistic",
        "eval_metric": ["error", "rmse"],
        "tree_method": "hist",
    },
    dtrain=D_train,
    evals=[[D_train, "Train"], (D_valid, "Valid")],
    feval=eval_error_metric,  # custom evaluation metric
    num_boost_round=100,
    callbacks=[early_stop],
)```
Hyper-parameter tuning

See https://github.com/coiled/dask-xgboost-nyctaxi for a set of examples of using XGBoost with dask and optuna.

Troubleshooting

- In some environments XGBoost might fail to resolve the IP address of the scheduler, a symptom is user receiving 
  `OSError: [Errno 99] Cannot assign requested address` error during training. A quick workaround is to specify the address explicitly. To do that dask config is used:
  ```python
  import dask
  from distributed import Client
  from xgboost import dask as dxgb
  # let xgboost know the scheduler address
  dask.config.set("
  xgboost.scheduler_address": "192.0.0.100"
  )
  with Client(scheduler_file="sched.json") as client:
    reg = dxgb.DaskXGBRegressor()
  # We can specify the port for XGBoost as well
  with dask.config.set("
  xgboost.scheduler_address": "192.0.0.100:12345"
  ):
    reg = dxgb.DaskXGBRegressor()
  ```

  Added in version 1.6.0.

- Please note that XGBoost requires a different port than dask. By default, on a unix-like system XGBoost uses the port 0 to find available ports, which may fail if a user is running in a restricted docker environment. In this case, please open additional ports in the container and specify it as in the above snippet.

- If you encounter a NCCL system error while training with GPU enabled, which usually includes the error message `NCCL failure: unhandled system error`, you can specify its network configuration using one of the environment variables listed in the NCCL document such as the `NCCL_SOCKET_IFNAME`. In addition, you can use `NCCL_DEBUG` to obtain debug logs.

- If NCCL fails to initialize in a container environment, it might be caused by limited system shared memory. With docker, one can try the flag: `--shm-size=4g`.

- MIG (Multi-Instance GPU) is not yet supported by NCCL. You will receive an error message that includes `Multiple processes within a communication group ...` upon initialization.

- Starting from version 2.1.0, to reduce the size of the binary wheel, the XGBoost package (installed using pip) loads NCCL from the environment instead of bundling it directly. This means that if you encounter an error message like “Failed to load nccl …”, it indicates that NCCL is not installed or properly configured in your environment.

To resolve this issue, you can install NCCL using pip:

```
pip install nvidia-nccl-cu12  # (or with any compatible CUDA version)
```

The default conda installation of XGBoost should not encounter this error. If you are using a customized XGBoost, please make sure one of the followings is true:

- XGBoost is NOT compiled with the `USE_DLOPEN_NCCL` flag.
- The `dmle_nccl_path` parameter is set to full NCCL path when initializing the collective.

Here are some additional tips for troubleshooting NCCL dependency issues:
- Check the NCCL installation path and verify that it’s installed correctly. We try to find NCCL by using
  from nvidia.nccl import lib in Python when XGBoost is installed using pip.
- Ensure that you have the correct CUDA version installed. NCCL requires a compatible CUDA version to
  function properly.
- If you are not using distributed training with XGBoost and yet see this error, please open an issue on GitHub.
- If you continue to encounter NCCL dependency issues, please open an issue on GitHub.

IPv6 Support

Added in version 1.7.0.

XGBoost has initial IPv6 support for the dask interface on Linux. Due to most of the cluster support for IPv6 is partial
(dual stack instead of IPv6 only), we require additional user configuration similar to Troubleshooting to help XGBoost
obtain the correct address information:

```python
import dask
from distributed import Client
from xgboost import dask as dxgb
# let xgboost know the scheduler address, use the same bracket format as dask.
with dask.config.set("
    'xgboost.scheduler_address': 
        '[fd20:b6f:f759:9800::]'
):
    with Client("[fd20:b6f:f759:9800::]") as client:
        reg = dxgb.DaskXGBRegressor(tree_method="hist")
```

When GPU is used, XGBoost employs NCCL as the underlying communication framework, which may require some
additional configuration via environment variable depending on the setting of the cluster. Please note that IPv6 support
is Unix only.

Why is the initialization of DaskDMatrix so slow and throws weird errors

The dask API in XGBoost requires construction of DaskDMatrix. With the Scikit-Learn interface, DaskDMatrix
is implicitly constructed for all input data during the fit or predict steps. You might have observed that
DaskDMatrix construction can take large amounts of time, and sometimes throws errors that don’t seem to be rel-
vant to DaskDMatrix. Here is a brief explanation for why. By default most dask computations are lazily evaluated,
which means that computation is not carried out until you explicitly ask for a result by, for example, calling compute().
See the previous link for details in dask, and this wiki for information on the general concept of lazy evaluation. The
DaskDMatrix constructor forces lazy computations to be evaluated, which means it’s where all your earlier computation
actually being carried out, including operations like dd.read_csv(). To isolate the computation in DaskDMatrix
from other lazy computations, one can explicitly wait for results of input data before constructing a DaskDMatrix. Also
dask’s diagnostics dashboard can be used to monitor what operations are currently being performed.

Reproducible Result

In a single node mode, we can always expect the same training result between runs as along as the underlying platforms
are the same. However, it’s difficult to obtain reproducible result in a distributed environment, since the tasks might
get different machine allocation or have different amount of available resources during different sessions. There are
heuristics and guidelines on how to achieve it but no proven method for guaranteeing such deterministic behavior. The
Dask interface in XGBoost tries to provide reproducible result with best effort. This section highlights some known
criteria and try to share some insights into the issue.

There are primarily two different tasks for XGBoost the carry out, training and inference. Inference is reproducible
given the same software and hardware along with the same run-time configurations. The remaining of this section will
focus on training.
Many of the challenges come from the fact that we are using approximation algorithms. The sketching algorithm used to find histogram bins is an approximation to the exact quantile algorithm, the $AUC$ metric in a distributed environment is an approximation to the exact $AUC$ score, and floating-point number is an approximation to real number. Floating-point is an issue as its summation is not associative, meaning $(a + b) + c$ does not necessarily equal to $a + (b + c)$, even though this property holds true for real number. As a result, whenever we change the order of a summation, the result can differ. This imposes the requirement that, in order to have reproducible output from XGBoost, the entire pipeline needs to be reproducible.

- The software stack is the same for each runs. This goes without saying. XGBoost might generate different outputs between different versions. This is expected as we might change the default value of hyper-parameter, or the parallel strategy that generates different floating-point result. We guarantee the correctness the algorithms, but there are lots of wiggle room for the final output. The situation is similar for many dependencies, for instance, the random number generator might differ from platform to platform.

- The hardware stack is the same for each runs. This includes the number of workers, and the amount of available resources on each worker. XGBoost can generate different results using different number of workers. This is caused by the approximation issue mentioned previously.

- Similar to the hardware constraint, the network topology is also a factor in final output. If we change topology the workers might be ordered differently, leading to different ordering of floating-point operations.

- The random seed used in various place of the pipeline.

- The partitioning of data needs to be reproducible. This is related to the available resources on each worker. Dask might partition the data differently for each run according to its own scheduling policy. For instance, if there are some additional tasks in the cluster while you are running the second training session for XGBoost, some of the workers might have constrained memory and Dask may not push the training data for XGBoost to that worker. This change in data partitioning can lead to different output models. If you are using a shared Dask cluster, then the result is likely to vary between runs.

- The operations performed on dataframes need to be reproducible. There are some operations like `DataFrame.merge` not being deterministic on parallel hardwares like GPU where the order of the index might differ from run to run.

It’s expected to have different results when training the model in a distributed environment than training the model using a single node due to aforementioned criteria.

**Memory Usage**

Here are some practices on reducing memory usage with dask and xgboost.

- In a distributed work flow, data is best loaded by dask collections directly instead of loaded by client process. When loading with client process is unavoidable, use `client.scatter` to distribute data from client process to workers. See [2] for a nice summary.

- When using GPU input, like dataframe loaded by `dask_cudf`, you can try `xgboost.dask.DaskQuantileDMatrix` as a drop in replacement for `DaskDMatrix` to reduce overall memory usage. See Example of training with Dask on GPU for an example.

- Use in-place prediction when possible.

1.4.13 Distributed XGBoost with PySpark

Starting from version 1.7.0, xgboost supports pyspark estimator APIs.

**Note**
The feature is still experimental and not yet ready for production use.

- **XGBoost PySpark Estimator**
  - SparkXGBRegressor
  - SparkXGBClassifier

- **XGBoost PySpark GPU support**

  - Write your PySpark application
  - Submit the PySpark application
  - Model Persistence
  - Accelerate the whole pipeline for xgboost pyspark
  - Advanced Usage

### XGBoost PySpark Estimator

**SparkXGBRegressor**

SparkXGBRegressor is a PySpark ML estimator. It implements the XGBoost classification algorithm based on XGBoost python library, and it can be used in PySpark Pipeline and PySpark ML meta algorithms like CrossValidator/TrainValidationSplit/OneVsRest.

We can create a SparkXGBRegressor estimator like:

```python
from xgboost.spark import SparkXGBRegressor
xgb_regressor = SparkXGBRegressor(
    features_col="features",
    label_col="label",
    num_workers=2,
)
```

The above snippet creates a spark estimator which can fit on a spark dataset, and return a spark model that can transform a spark dataset and generate dataset with prediction column. We can set almost all of xgboost sklearn estimator parameters as SparkXGBRegressor parameters, but some parameter such as nthread is forbidden in spark estimator, and some parameters are replaced with pyspark specific parameters such as weight_col, validation_indicator_col, for details please see SparkXGBRegressor doc.

The following code snippet shows how to train a spark xgboost regressor model, first we need to prepare a training dataset as a spark dataframe contains “label” column and “features” column(s), the “features” column(s) must be pyspark.ml.linalg.Vector type or spark array type or a list of feature column names.
The following code snippet shows how to predict test data using a spark xgboost regressor model, first we need to prepare a test dataset as a spark dataframe contains “features” and “label” column, the “features” column must be pyspark.ml.linalg.Vector type or spark array type.

```python
xgb_regressor_model = xgb_regressor.fit(train_spark_dataframe)
```

The above snippet code returns a `transformed_test_spark_dataframe` that contains the input dataset columns and an appended column “prediction” representing the prediction results.

**SparkXGBClassifier**

`SparkXGBClassifier` estimator has similar API with `SparkXGBRegressor`, but it has some pyspark classifier specific params, e.g. `raw_prediction_col` and `probability_col` parameters. Correspondingly, by default, `SparkXGBClassifierModel` transforming test dataset will generate result dataset with 3 new columns:

- “prediction”: represents the predicted label.
- “raw_prediction”: represents the output margin values.
- “probability”: represents the prediction probability on each label.

**XGBoost PySpark GPU support**

XGBoost PySpark fully supports GPU acceleration. Users are not only able to enable efficient training but also utilize their GPUs for the whole PySpark pipeline including ETL and inference. In below sections, we will walk through an example of training on a Spark standalone cluster with GPU support. To get started, first we need to install some additional packages, then we can set the device parameter to cuda or gpu.

**Prepare the necessary packages**

Aside from the PySpark and XGBoost modules, we also need the cuDF package for handling Spark dataframe. We recommend using either Conda or Virtualenv to manage python dependencies for PySpark jobs. Please refer to How to Manage Python Dependencies in PySpark for more details on PySpark dependency management.

In short, to create a Python environment that can be sent to a remote cluster using virtualenv and pip:

```bash
python -m venv xgboost_env
source xgboost_env/bin/activate
pip install pyarrow pandas venv-pack xgboost
# https://docs.rapids.ai/install#pip-install
pip install cudf-cu11 --extra-index-url=https://pypi.nvidia.com
venv-pack -o xgboost_env.tar.gz
```

With Conda:

```bash
conda create -y -n xgboost_env -c conda-forge conda-pack python=3.9
conda activate xgboost_env
# use conda when the supported version of xgboost (1.7) is released on conda-forge
pip install xgboost
conda install cudf pyarrow pandas -c rapids -c nvidia -c conda-forge
conda pack -f -o xgboost_env.tar.gz
```
Write your PySpark application

Below snippet is a small example for training xgboost model with PySpark. Notice that we are using a list of feature names instead of vector type as the input. The parameter "device=cuda" specifically indicates that the training will be performed on a GPU.

```python
from xgboost.spark import SparkXGBRegressor
spark = SparkSession.builder.getOrCreate()

# read data into spark dataframe
train_data_path = "xxxx/train"
train_df = spark.read.parquet(data_path)

test_data_path = "xxxx/test"
test_df = spark.read.parquet(test_data_path)

# assume the label column is named "class"
label_name = "class"

# get a list with feature column names
feature_names = [x.name for x in train_df.schema if x.name != label_name]

# create a xgboost pyspark regressor estimator and set device="cuda"
regressor = SparkXGBRegressor(
    features_col=feature_names,
    label_col=label_name,
    num_workers=2,
    device="cuda",
)

# train and return the model
model = regressor.fit(train_df)

# predict on test data
predict_df = model.transform(test_df)
predict_df.show()
```

Like other distributed interfaces, the device parameter doesn't support specifying ordinal as GPUs are managed by Spark instead of XGBoost (good: device=cuda, bad: device=cuda:0).

Submit the PySpark application

Assuming you have configured the Spark standalone cluster with GPU support. Otherwise, please refer to spark standalone configuration with GPU support.

Starting from XGBoost 2.0.1, stage-level scheduling is automatically enabled. Therefore, if you are using Spark standalone cluster version 3.4.0 or higher, we strongly recommend configuring the "spark.task.resource.gpu.amount" as a fractional value. This will enable running multiple tasks in parallel during the ETL phase. An example configuration would be "spark.task.resource.gpu.amount=1/spark.executor.cores". However, if you are using a XGBoost version earlier than 2.0.1 or a Spark standalone cluster version below 3.4.0, you still need to set "spark.task.resource.gpu.amount" equal to "spark.executor.resource.gpu.amount".
As of now, the stage-level scheduling feature in XGBoost is limited to the Spark standalone cluster mode. However, we have plans to expand its compatibility to YARN and Kubernetes once Spark 3.5.1 is officially released.

```bash
export PYSPARK_DRIVER_PYTHON=python
export PYSPARK_PYTHON=./environment/bin/python

spark-submit \
  --master spark://<master-ip>:7077 \n  --conf spark.executor.cores=12 \n  --conf spark.task.cpus=1 \n  --conf spark.executor.resource.gpu.amount=1 \n  --conf spark.task.resource.gpu.amount=0.08 \n  --archives xgboost_env.tar.gz#environment 
xgboost_app.py
```

The above command submits the xgboost pyspark application with the python environment created by pip or conda, specifying a request for 1 GPU and 12 CPUs per executor. So you can see, a total of 12 tasks per executor will be executed concurrently during the ETL phase.

## Model Persistence

Similar to standard PySpark ml estimators, one can persist and reuse the model with `save` and `load` methods:

```python
regressor = SparkXGBRegressor()
model = regressor.fit(train_df)
# save the model
model.save("/tmp/xgboost-pyspark-model")
# load the model
model2 = SparkXGBRankerModel.load("/tmp/xgboost-pyspark-model")
```

To export the underlying booster model used by XGBoost:

```python
regressor = SparkXGBRegressor()
model = regressor.fit(train_df)
# the same booster object returned by xgboost.train
booster: xgb.Booster = model.get_booster()
booster.predict(...)
booster.save_model("model.json") # or model.ubj, depending on your choice of format.
```

This booster is not only shared by other Python interfaces but also used by all the XGBoost bindings including the C, Java, and the R package. Lastly, one can extract the booster file directly from a saved spark estimator without going through the getter:

```python
import xgboost as xgb
bst = xgb.Booster()
# Loading the model saved in previous snippet
bst.load_model("/tmp/xgboost-pyspark-model/model/part-00000")
```
Accelerate the whole pipeline for xgboost pyspark

With RAPIDS Accelerator for Apache Spark, you can leverage GPUs to accelerate the whole pipeline (ETL, Train, Transform) for xgboost pyspark without the need for any code modifications. Likewise, you have the option to configure the "spark.task.resource.gpu.amount" setting as a fractional value, enabling a higher number of tasks to be executed in parallel during the ETL phase. Please refer to Submit the PySpark application for more details.

An example submit command is shown below with additional spark configurations and dependencies:

```bash
export PYSPARK_DRIVER_PYTHON=python
export PYSPARK_PYTHON=./environment/bin/python

spark-submit \
  --master spark://<master-ip>:7077 \
  --conf spark.executor.cores=12 \
  --conf spark.task.cpus=1 \
  --conf spark.task.resource.gpu.amount=1 \
  --conf spark.task.resource.gpu.amount=0.08 \
  --packages com.nvidia:rapids-4-spark_2.12:24.04.1 \
  --conf spark.plugins=com.nvidia.spark.SQLPlugin \
  --conf spark.sql.execution.arrow.maxRecordsPerBatch=1000000 \
  --archives xgboost_env.tar.gz#environment \
  xgboost_app.py
```

When rapids plugin is enabled, both of the JVM rapids plugin and the cuDF Python package are required. More configuration options can be found in the RAPIDS link above along with details on the plugin.

Advanced Usage

XGBoost needs to repartition the input dataset to the num_workers to ensure there will be num_workers training tasks running at the same time. However, repartition is a costly operation.

If there is a scenario where reading the data from source and directly fitting it to XGBoost without introducing the shuffle stage, users can avoid the need for repartitioning by setting the Spark configuration parameters spark.sql.files.maxPartitionNum and spark.sql.files.minPartitionNum to num_workers. This tells Spark to automatically partition the dataset into the desired number of partitions.

However, if the input dataset is skewed (i.e. the data is not evenly distributed), setting the partition number to num_workers may not be efficient. In this case, users can set the force_repartition=true option to explicitly force XGBoost to repartition the dataset, even if the partition number is already equal to num_workers. This ensures the data is evenly distributed across the workers.

1.4.14 Distributed XGBoost with Ray

Ray is a general purpose distributed execution framework. Ray can be used to scale computations from a single node to a cluster of hundreds of nodes without changing any code.

The Python bindings of Ray come with a collection of well maintained machine learning libraries for hyperparameter optimization and model serving.

The XGBoost-Ray project provides an interface to run XGBoost training and prediction jobs on a Ray cluster. It allows to utilize distributed data representations, such as Modin dataframes, as well as distributed loading from cloud storage (e.g. Parquet files).
XGBoost-Ray integrates well with hyperparameter optimization library Ray Tune, and implements advanced fault tolerance handling mechanisms. With Ray you can scale your training jobs to hundreds of nodes just by adding new nodes to a cluster. You can also use Ray to leverage multi GPU XGBoost training.

**Installing and starting Ray**

Ray can be installed from PyPI like this:

```
pip install ray
```

If you’re using Ray on a single machine, you don’t need to do anything else - XGBoost-Ray will automatically start a local Ray cluster when used.

If you want to use Ray on a cluster, you can use the Ray cluster launcher.

**Installing XGBoost-Ray**

XGBoost-Ray is also available via PyPI:

```
pip install xgboost_ray
```

This will install all dependencies needed to run XGBoost on Ray, including Ray itself if it hasn’t been installed before.

**Using XGBoost-Ray for training and prediction**

XGBoost-Ray uses the same API as core XGBoost. There are only two differences:

1. Instead of using a `xgboost.DMatrix`, you’ll use a `xgboost_ray.RayDMatrix` object
2. There is an additional `ray_params` parameter that you can use to configure distributed training.

**Simple training example**

To run this simple example, you’ll need to install scikit-learn (with `pip install sklearn`).

In this example, we will load the breast cancer dataset and train a binary classifier using two actors.

```
from xgboost_ray import RayDMatrix, RayParams, train
from sklearn.datasets import load_breast_cancer

train_x, train_y = load_breast_cancer(return_X_y=True)
train_set = RayDMatrix(train_x, train_y)

evals_result = {}
bst = train(
    {
        "objective": "binary:logistic",
        "eval_metric": ["logloss", "error"],
    },
    train_set,
evals_result=evals_result,
evals=[(train_set, "train")],
verbose_eval=False,
)
```

(continues on next page)
The only differences compared to the non-distributed API are the import statement (xgboost_ray instead of xgboost), using the RayDMatrix instead of the DMatrix, and passing a RayParams object.

The return object is a regular xgboost.Booster instance.

```python
from xgboost_ray import RayDMatrix, RayParams, predict
from sklearn.datasets import load_breast_cancer
import xgboost as xgb
data, labels = load_breast_cancer(return_X_y=True)
dpred = RayDMatrix(data, labels)
bst = xgb.Booster(model_file="model.xgb")
pred_ray = predict(bst, dpred, ray_params=RayParams(num_actors=2))
print(pred_ray)
```

In this example, the data will be split across two actors. The result array will integrate this data in the correct order.

**The RayParams object**

The RayParams object is used to configure various settings relating to the distributed training.

```python
class xgboost_ray.RayParams(num_actors=0, cpus_per_actor=0, gpus_per_actor=-1,
resources_per_actor=None, elastic_training=False, max_failed_actors=0,
max_actor_restarts=0, checkpoint_frequency=5, distributed_callbacks=None,
verbose=None, placement_options=None)
```

Parameters to configure Ray-specific behavior.

- **num_actors** ([int](https://docs.python.org/3/library/typing.html#typing.Int)) – Number of parallel Ray actors.
- **cpus_per_actor** ([int](https://docs.python.org/3/library/typing.html#typing.Int)) – Number of CPUs to be used per Ray actor.
- **gpus_per_actor** ([int](https://docs.python.org/3/library/typing.html#typing.Int)) – Number of GPUs to be used per Ray actor.
- **resources_per_actor** ([Dict](https://docs.python.org/3/library/typing.html#typing.Dict) | [None](https://docs.python.org/3/library/typing.html#typing.None)) – Dict of additional resources required per Ray actor.
- **elastic_training** ([bool](https://docs.python.org/3/library/typing.html#typing.Boolean)) – If True, training will continue with fewer actors if an actor fails. Default False.
- **max_failed_actors** ([int](https://docs.python.org/3/library/typing.html#typing.Int)) – If elastic_training is True, this specifies the maximum number of failed actors with which we still continue training.
• **max_actor_restarts** *(int)* – Number of retries when Ray actors fail. Defaults to 0 (no retries). Set to -1 for unlimited retries.

• **checkpoint_frequency** *(int)* – How often to save checkpoints. Defaults to 5 (every 5th iteration).

• **verbose** *(bool | None)* – Whether to output Ray-specific info messages during training/prediction.

• **placement_options** *(Dict[str, Any])* – Optional kwargs to pass to PlacementGroupFactory in get_tune_resources().

• **distributed_callbacks** *(List[DistributedCallback] | None)*

PublicAPI (beta): This API is in beta and may change before becoming stable.

**Multi GPU training**

Ray automatically detects GPUs on cluster nodes. In order to start training on multiple GPUs, all you have to do is to set the `gpus_per_actor` parameter of the `RayParams` object, as well as the `num_actors` parameter for multiple GPUs:

```python
def ray_params = RayParams(
    num_actors=4,
    gpus_per_actor=1,
)
```

This will train on four GPUs in parallel.

Note that it usually does not make sense to allocate more than one GPU per actor, as XGBoost relies on distributed libraries such as Dask or Ray to utilize multi GPU training.

**Setting the number of CPUs per actor**

XGBoost natively utilizes multi threading to speed up computations. Thus if your are training on CPUs only, there is likely no benefit in using more than one actor per node. In that case, assuming you have a cluster of homogeneous nodes, set the number of CPUs per actor to the number of CPUs available on each node, and the number of actors to the number of nodes.

If you are using multi GPU training on a single node, divide the number of available CPUs evenly across all actors. For instance, if you have 16 CPUs and 4 GPUs available, each actor should access 1 GPU and 4 CPUs.

If you are using a cluster of heterogeneous nodes (with different amounts of CPUs), you might just want to use the greatest common divisor for the number of CPUs per actor. E.g. if you have a cluster of three nodes with 4, 8, and 12 CPUs, respectively, you'd start 6 actors with 4 CPUs each for maximum CPU utilization.

**Fault tolerance**

XGBoost-Ray supports two fault tolerance modes. In **non-elastic training**, whenever a training actor dies (e.g. because the node goes down), the training job will stop, XGBoost-Ray will wait for the actor (or its resources) to become available again (this might be on a different node), and then continue training once all actors are back.

In **elastic-training**, whenever a training actor dies, the rest of the actors continue training without the dead actor. If the actor comes back, it will be re-integrated into training again.

Please note that in elastic-training this means that you will train on fewer data for some time. The benefit is that you can continue training even if a node goes away for the remainder of the training run, and don’t have to wait until it is back.
up again. In practice this usually leads to a very minor decrease in accuracy but a much shorter training time compared to non-elastic training.

Both training modes can be configured using the respective `RayParams` parameters.

Hyperparameter optimization

XGBoost-Ray integrates well with hyperparameter optimization framework Ray Tune. Ray Tune uses Ray to start multiple distributed trials with different hyperparameter configurations. If used with XGBoost-Ray, these trials will then start their own distributed training jobs.

XGBoost-Ray automatically reports evaluation results back to Ray Tune. There’s only a few things you need to do:

1. Put your XGBoost-Ray training call into a function accepting parameter configurations (`train_model` in the example below).
2. Create a `RayParams` object (`ray_params` in the example below).
3. Define the parameter search space (`config` dict in the example below).
4. Call `tune.run()`:
   - The `metric` parameter should contain the metric you’d like to optimize. Usually this consists of the prefix passed to the `evals` argument of `xgboost_ray.train()`, and an `eval_metric` passed in the XGBoost parameters (`train-error` in the example below).
   - The `mode` should either be `min` or `max`, depending on whether you’d like to minimize or maximize the metric
   - The `resources_per_actor` should be set using `ray_params.get_tune_resources()`. This will make sure that each trial has the necessary resources available to start their distributed training jobs.

```python
from xgboost_ray import RayDMatrix, RayParams, train
from sklearn.datasets import load_breast_cancer

num_actors = 4
num_cpus_per_actor = 1

ray_params = RayParams(
    num_actors=num_actors, cpus_per_actor=num_cpus_per_actor)

def train_model(config):
    train_x, train_y = load_breast_cancer(return_X_y=True)
    train_set = RayDMatrix(train_x, train_y)

    evals_result = {}
    bst = train(
        params=config,
        dtrain=train_set,
        evals_result=evals_result,
        evals=[(train_set, "train")],
        verbose_eval=False,
        ray_params=ray_params)
    bst.save_model("model.xgb")

from ray import tune
```

(continues on next page)
# Specify the hyperparameter search space.
config = {
    "tree_method": "approx",
    "objective": "binary:logistic",
    "eval_metric": ["logloss", "error"],
    "eta": tune.loguniform(1e-4, 1e-1),
    "subsample": tune.uniform(0.5, 1.0),
    "max_depth": tune.randint(1, 9)
}

# Make sure to use the `get_tune_resources` method to set the `resources_per_trial`
analysis = tune.run(
    train_model,
    config=config,
    metric="train-error",
    mode="min",
    num_samples=4,
    resources_per_trial=ray_params.get_tune_resources())
print("Best hyperparameters", analysis.best_config)

Ray Tune supports various search algorithms and libraries (e.g. BayesOpt, Tree-Parzen estimators), smart schedulers like successive halving, and other features. Please refer to the Ray Tune documentation for more information.

1.4.15 Using XGBoost External Memory Version

When working with large datasets, training XGBoost models can be challenging as the entire dataset needs to be loaded into memory. This can be costly and sometimes infeasible. Starting from 1.5, users can define a custom iterator to load data in chunks for running XGBoost algorithms. External memory can be used for both training and prediction, but training is the primary use case and it will be our focus in this tutorial. For prediction and evaluation, users can iterate through the data themselves while training requires the full dataset to be loaded into the memory.

During training, there are two different modes for external memory support available in XGBoost, one for CPU-based algorithms like hist and approx, another one for the GPU-based training algorithm. We will introduce them in the following sections.

Note

Training on data from external memory is not supported by the exact tree method.
The feature is still experimental as of 2.0. The performance is not well optimized.

The external memory support has gone through multiple iterations and is still under heavy development. Like the `QuantileDMatrix` with `DataIter`, XGBoost loads data batch-by-batch using a custom iterator supplied by the user. However, unlike the `QuantileDMatrix`, external memory will not concatenate the batches unless GPU is used (it uses a hybrid approach, more details follow). Instead, it will cache all batches on the external memory and fetch them on-demand. Go to the end of the document to see a comparison between `QuantileDMatrix` and external memory.

**Data Iterator**

Starting from XGBoost 1.5, users can define their own data loader using Python or C interface. There are some examples in the demo directory for quick start. This is a generalized version of text input external memory, where users no longer need to prepare a text file that XGBoost recognizes. To enable the feature, users need to define a data iterator with 2 class methods: `next` and `reset`, then pass it into the `DMatrix` constructor.

```python
import os
from typing import List, Callable
import xgboost
from sklearn.datasets import load_svmlight_file

class Iterator(xgboost.DataIter):
    def __init__(self, svm_file_paths: List[str]):
        self._file_paths = svm_file_paths
        self._it = 0
        # XGBoost will generate some cache files under current directory with the prefix "cache"
        super().__init__(cache_prefix=os.path.join('.', 'cache'))

    def next(self, input_data: Callable):
        """Advance the iterator by 1 step and pass the data to XGBoost. This function is called by XGBoost during the construction of `DMatrix`"

        if self._it == len(self._file_paths):
            # return 0 to let XGBoost know this is the end of iteration
            return 0

            # input_data is a function passed in by XGBoost who has the exact same signature of # `DMatrix`
            X, y = load_svmlight_file(self._file_paths[self._it])
            input_data(data=X, label=y)
            self._it += 1
            # Return 1 to let XGBoost know we haven't seen all the files yet.
            return 1

    def reset(self):
        """Reset the iterator to its beginning""
        self._it = 0
```

(continues on next page)
it = Iterator(["file_0.svm", "file_1.svm", "file_2.svm")
Xy = xgboost.DMatrix(it)

# The `approx` also work, but with low performance. GPU implementation is different from CPU.
# as noted in following sections.
booster = xgboost.train({'tree_method': "hist"}, Xy)

The above snippet is a simplified version of Experimental support for external memory. For an example in C, please see demo/c-api/external-memory/. The iterator is the common interface for using external memory with XGBoost, you can pass the resulting DMatrix object for training, prediction, and evaluation.

It is important to set the batch size based on the memory available. A good starting point is to set the batch size to 10GB per batch if you have 64GB of memory. It is not recommended to set small batch sizes like 32 samples per batch, as this can seriously hurt performance in gradient boosting.

**CPU Version**

In the previous section, we demonstrated how to train a tree-based model using the hist tree method on a CPU. This method involves iterating through data batches stored in a cache during tree construction. For optimal performance, we recommend using the grow_policy=depthwise setting, which allows XGBoost to build an entire layer of tree nodes with only a few batch iterations. Conversely, using the lossguide policy requires XGBoost to iterate over the data set for each tree node, resulting in slower performance.

If external memory is used, the performance of CPU training is limited by IO (input/output) speed. This means that the disk IO speed primarily determines the training speed. During benchmarking, we used an NVMe connected to a PCIe-4 slot, other types of storage can be too slow for practical usage. In addition, your system may perform caching to reduce the overhead of file reading.

**GPU Version (GPU Hist tree method)**

External memory is supported by GPU algorithms (i.e. when device is set to cuda). However, the algorithm used for GPU is different from the one used for CPU. When training on a CPU, the tree method iterates through all batches from external memory for each step of the tree construction algorithm. On the other hand, the GPU algorithm uses a hybrid approach. It iterates through the data during the beginning of each iteration and concatenates all batches into one in GPU memory for performance reasons. To reduce overall memory usage, users can utilize subsampling. The GPU hist tree method supports gradient-based sampling, enabling users to set a low sampling rate without compromising accuracy.

param = {
    ...
    'subsample': 0.2,
    'sampling_method': 'gradient_based',
}

For more information about the sampling algorithm and its use in external memory training, see this paper.

⚠️ **Warning**

When GPU is running out of memory during iteration on external memory, user might receive a segfault instead of an OOM exception.
Remarks

When using external memory with XGBoost, data is divided into smaller chunks so that only a fraction of it needs to be stored in memory at any given time. It’s important to note that this method only applies to the predictor data \(X\), while other data, like labels and internal runtime structures are concatenated. This means that memory reduction is most effective when dealing with wide datasets where \(X\) is significantly larger in size compared to other data like \(y\), while it has little impact on slim datasets.

As one might expect, fetching data on-demand puts significant pressure on the storage device. Today’s computing device can process way more data than a storage can read in a single unit of time. The ratio is at order of magnitudes. An GPU is capable of processing hundred of Gigabytes of floating-point data in a split second. On the other hand, a four-lane NVMe storage connected to a PCIe-4 slot usually has about 6GB/s of data transfer rate. As a result, the training is likely to be severely bounded by your storage device. Before adopting the external memory solution, some back-of-envelop calculations might help you see whether it’s viable. For instance, if your NVMe drive can transfer 4GB (a fairly practical number) of data per second and you have a 100GB of data in compressed XGBoost cache (which corresponds to a dense float32 numpy array with the size of 200GB, give or take). A tree with depth 8 needs at least 16 iterations through the data when the parameter is right. You need about 14 minutes to train a single tree without accounting for some other overheads and assume the computation overlaps with the IO. If your dataset happens to have TB-level size, then you might need thousands of trees to get a generalized model. These calculations can help you get an estimate on the expected training time.

However, sometimes we can ameliorate this limitation. One should also consider that the OS (mostly talking about the Linux kernel) can usually cache the data on host memory. It only evicts pages when new data comes in and there’s no room left. In practice, at least some portion of the data can persist on the host memory throughout the entire training session. We are aware of this cache when optimizing the external memory fetcher. The compressed cache is usually smaller than the raw input data, especially when the input is dense without any missing value. If the host memory can fit a significant portion of this compressed cache, then the performance should be decent after initialization. Our development so far focus on two fronts of optimization for external memory:

- Avoid iterating through the data whenever appropriate.
- If the OS can cache the data, the performance should be close to in-core training.

Starting with XGBoost 2.0, the implementation of external memory uses mmap. It is not tested against system errors like disconnected network devices (SIGBUS). In the face of a bus error, you will see a hard crash and need to clean up the cache files. If the training session might take a long time and you are using solutions like NVMe-oF, we recommend checkpointing your model periodically. Also, it’s worth noting that most tests have been conducted on Linux distributions.

Another important point to keep in mind is that creating the initial cache for XGBoost may take some time. The interface to external memory is through custom iterators, which we can not assume to be thread-safe. Therefore, initialization is performed sequentially. Using the `config_context()` with `verbosity=2` can give you some information on what XGBoost is doing during the wait if you don’t mind the extra output.

**Compared to the QuantileDMatrix**

Passing an iterator to the `QuantileDMatrix` enables direct construction of `QuantileDMatrix` with data chunks. On the other hand, if it’s passed to `DMatrix`, it instead enables the external memory feature. The `QuantileDMatrix` concatenates the data on memory after compression and doesn’t fetch data during training. On the other hand, the external memory `DMatrix` fetches data batches from external memory on-demand. Use the `QuantileDMatrix` (with iterator if necessary) when you can fit most of your data in memory. The training would be an order of magnitude faster than using external memory.
Text File Inputs

⚠️ **Warning**

This is the original form of external memory support before 1.5, users are encouraged to use custom data iterator instead.

There is no big difference between using external memory version of text input and the in-memory version. The only difference is the filename format.

The external memory version takes in the following **URI** format:

```
filename?format=libsvm#cacheprefix
```

The `filename` is the normal path to LIBSVM format file you want to load in, and `cacheprefix` is a path to a cache file that XGBoost will use for caching preprocessed data in binary form.

To load from csv files, use the following syntax:

```
filename.csv?format=csv&label_column=0#cacheprefix
```

where `label_column` should point to the csv column acting as the label.

If you have a dataset stored in a file similar to `demo/data/agaricus.txt.train` with LIBSVM format, the external memory support can be enabled by:

```
dtrain = DMatrix('../data/agaricus.txt.train?format=libsvm#dtrain.cache')
```

XGBoost will first load `agaricus.txt.train` in, preprocess it, then write to a new file named `dtrain.cache` as an on disk cache for storing preprocessed data in an internal binary format. For more notes about text input formats, see [Text Input Format of DMatrix](#)

For CLI version, simply add the cache suffix, e.g. `../data/agaricus.txt.train?format=libsvm#dtrain.cache`.

### 1.4.16 C API Tutorial

In this tutorial, we are going to install XGBoost library & configure the CMakeLists.txt file of our C/C++ application to link XGBoost library with our application. Later on, we will see some useful tips for using C API and code snippets as examples to use various functions available in C API to perform basic task like loading, training model & predicting on test dataset. For API reference, please visit [XGBoost C Package](#)

- **Requirements**
- **Install XGBoost on conda environment**
- **Configure CMakeLists.txt file of your application to link with XGBoost**
- **Useful Tips To Remember**
- **Sample examples along with Code snippet to use C API functions**

---

**1.4. XGBoost Tutorials**
Requirements

Install CMake - Follow the cmake installation documentation for instructions. Install Conda - Follow the conda installation documentation for instructions.

Install XGBoost on conda environment

Run the following commands on your terminal. The below commands will install the XGBoost in your XGBoost folder of the repository cloned:

```bash
# clone the XGBoost repository & its submodules
git clone --recursive https://github.com/dmlc/xgboost
cd xgboost
mkdir build
cd build
# Activate the Conda environment, into which we'll install XGBoost
conda activate [env_name]
# Build the compiled version of XGBoost inside the build folder
cmake .. -DCMAKE_INSTALL_PREFIX=$CONDA_PREFIX
# install XGBoost in your conda environment (usually under [your home directory]/miniconda3)
make install
```

Configure CMakeList.txt file of your application to link with XGBoost

Here, we assume that your C++ application is using CMake for builds.

Use `find_package()` and `target_link_libraries()` in your application's CMakeList.txt to link with the XGBoost library:

```cpp
cmake_minimum_required(VERSION 3.18)
project(your_project_name LANGUAGES C CXX VERSION your_project_version)
find_package(xgboost REQUIRED)
add_executable(your_project_name /path/to/project_file.c)
target_link_libraries(your_project_name xgboost::xgboost)
```

To ensure that CMake can locate the XGBoost library, supply `-DCMAKE_PREFIX_PATH=$CONDA_PREFIX` argument when invoking CMake. This option instructs CMake to locate the XGBoost library in `$CONDA_PREFIX`, which is where your Conda environment is located.

```bash
# Navigate to the build directory for your application
cd build
# Activate the Conda environment where we previously installed XGBoost
conda activate [env_name]
# Invoke CMake with CMAKE_PREFIX_PATH
cmake .. -DCMAKE_PREFIX_PATH=$CONDA_PREFIX
# Build your application
make
```
Useful Tips To Remember

Below are some useful tips while using C API:

1. Error handling: Always check the return value of the C API functions.
   a. In a C application: Use the following macro to guard all calls to XGBoost’s C API functions. The macro prints all the error/ exception occurred:

   ```c
   #define safe_xgboost(call) { 
   int err = (call); 
   if (err != 0) { 
     fprintf(stderr, "%s:%d: error in %s: %sn", __FILE__, __LINE__, #call, 
     XGBGetLastError()); 
     exit(1); 
   } 
   }
   ```

   In your application, wrap all C API function calls with the macro as follows:

   ```c
   DMatrixHandle train;
   safe_xgboost(XGDMatrixCreateFromFile("/path/to/training/dataset/", silent, &train));
   ```

   b. In a C++ application: modify the macro `safe_xgboost` to throw an exception upon an error.

   ```c
   #define safe_xgboost(call) { 
   int err = (call); 
   if (err != 0) { 
     throw std::runtime_error(std::string(__FILE__) + ":" + std::to_string(__LINE__) + ": error in " + #call + ":" + XGBGetLastError()); 
   } 
   }
   ```

   c. Assertion technique: It works both in C/ C++. If expression evaluates to 0 (false), then the expression, source code filename, and line number are sent to the standard error, and then abort() function is called. It can be used to test assumptions made by you in the code.

   ```c
   DMatrixHandle dmat;
   assert( XGDMatrixCreateFromFile("training.data.libsvm", 0, &dmat) == 0);
   ```

2. Always remember to free the allocated space by BoosterHandle & DMatrixHandle appropriately:
xgboost, Release 2.1.1

(continued from previous page)

XGBoosterFree(booster);

14
15

DMatrixHandle DMatrixHandle_param;

16
17

// do something with DMatrixHandle_param

18
19

// free the memory
XGDMatrixFree(DMatrixHandle_param);

20
21
22

return 0;

23
24

}
3. For tree models, it is important to use consistent data formats during training and scoring/ predicting otherwise
it will result in wrong outputs. Example if we our training data is in dense matrix format then your prediction
dataset should also be a dense matrix or if training in libsvm format then dataset for prediction should also
be in libsvm format.
4. Always use strings for setting values to the parameters in booster handle object. The parameter value can be of
any data type (e.g. int, char, float, double, etc), but they should always be encoded as strings.
BoosterHandle booster;
XGBoosterSetParam(booster, "parameter_name", "0.1");

Sample examples along with Code snippet to use C API functions
1. If the dataset is available in a file,
XGDMatrixCreateFromFile()

it can be loaded into a DMatrix object using the

DMatrixHandle data; // handle to DMatrix
// Load the data from file & store it in data variable of DMatrixHandle datatype
safe_xgboost(XGDMatrixCreateFromFile("/path/to/file/filename", silent, &data));
2. You can also create a DMatrix object from a 2D Matrix using the XGDMatrixCreateFromMat()
1
2

// 1D matrix
const int data1[] = { 0, 0, 1, 0, 1, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1, 0, 0,␣
˓→1, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0 };

3
4
5
6

7
8
9
10
11
12
13

// 2D matrix
const int ROWS = 5, COLS = 3;
const int data2[ROWS][COLS] = { {1, 2, 3}, {2, 4, 6}, {3, -1, 9}, {4, 8, -1}, {2, 5, 1},
˓→{0, 1, 5} };
DMatrixHandle dmatrix1, dmatrix2;
// Pass the matrix, no of rows & columns contained in the matrix variable
// here '0' represents the missing value in the matrix dataset
// dmatrix variable will contain the created DMatrix using it
safe_xgboost(XGDMatrixCreateFromMat(data1, 1, 50, 0, &dmatrix));
// here -1 represents the missing value in the matrix dataset
safe_xgboost(XGDMatrixCreateFromMat(data2, ROWS, COLS, -1, &dmatrix2));
3. Create a Booster object for training & testing on dataset using XGBoosterCreate()

94

Chapter 1. Contents


BoosterHandle booster;
const int eval_dmats_size;
// We assume that training and test data have been loaded into 'train' and 'test'
DMatrixHandle eval_dmats[eval_dmats_size] = {train, test};
safe_xgboost(XGBoosterCreate(eval_dmats, eval_dmats_size, &booster));

4. For each DMatrix object, set the labels using XGDMatrixSetFloatInfo(). Later you can access the label using XGDMatrixGetFloatInfo().

const int ROWS=5, COLS=3;
const int data[ROWS][COLS] = { {1, 2, 3}, {2, 4, 6}, {3, -1, 9}, {4, 8, -1}, {2, 5, 1},
                   {0, 1, 5} };;
DMatrixHandle dmatrix;
safe_xgboost(XGDMatrixCreateFromMat(data, ROWS, COLS, -1, &dmatrix));
// variable to store labels for the dataset created from above matrix
float labels[ROWS];

for (int i = 0; i < ROWS; i++) {
    labels[i] = i;
}

// Loading the labels
safe_xgboost(XGDMatrixSetFloatInfo(dmatrix, "label", labels, ROWS));

// reading the labels and store the length of the result
bst_ulong result_len;

// labels result
const float *result;

safe_xgboost(XGDMatrixGetFloatInfo(dmatrix, "label", &result_len, &result));

for(unsigned int i = 0; i < result_len; i++) {
    printf("label[%i] = %f\n", i, result[i]);
}

5. Set the parameters for the Booster object according to the requirement using XGBoosterSetParam(). Check out the full list of parameters available here.

BoosterHandle booster;
safe_xgboost(XGBoosterSetParam(booster, "booster", "gblinear"));
// default max_depth =6
safe_xgboost(XGBoosterSetParam(booster, "max_depth", "3"));
// default eta = 0.3
safe_xgboost(XGBoosterSetParam(booster, "eta", "0.1"));

6. Train & evaluate the model using XGBoosterUpdateOneIter() and XGBoosterEvalOneIter() respectively.

int num_of_iterations = 20;
const char* eval_names[eval_dmats_size] = {"train", "test"};
const char* eval_result = NULL;

(continues on next page)
for (int i = 0; i < num_of_iterations; ++i) {
  // Update the model performance for each iteration
  safe_xgboost(XGBoosterUpdateOneIter(booster, i, train));

  // Give the statistics for the learner for training & testing dataset in terms of error after each iteration
  safe_xgboost(XGBoosterEvalOneIter(booster, i, eval_dmats, eval_names, eval_dmats_size, &eval_result));
  printf("%s\n", eval_result);
}

Note

For customized loss function, use XGBoosterBoostOneIter() instead and manually specify the gradient and 2nd order gradient.

7. Predict the result on a test set using XGBoosterPredictFromDMatrix()

char const config[] =
  "{"training": false, "type": 0, "iteration_begin": 0, "iteration_end": 0, "strict_shape": false}"
/* Shape of output prediction */
uint64_t const* out_shape;
/* Dimension of output prediction */
uint64_t out_dim;
/* Pointer to a thread local contiguous array, assigned in prediction function. */
float const* out_result = NULL;
safe_xgboost(
  XGBoosterPredictFromDMatrix(booster, dmatrix, config, &out_shape, &out_dim, &out_result));

for (unsigned int i = 0; i < output_length; i++){
  printf("prediction[%i] = %f \n", i, output_result[i]);
}

8. Get the number of features in your dataset using XGBoosterGetNumFeature().

bst_ulong num_of_features = 0;

// Assuming booster variable of type BoosterHandle is already declared
// and dataset is loaded and trained on booster
// storing the results in num_of_features variable
safe_xgboost(XGBoosterGetNumFeature(booster, &num_of_features));

// Printing number of features by type conversion of num_of_features variable from bst_ulong to unsigned long
printf("num_feature: %lu\n", (unsigned long)(num_of_features));

9. Save the model using XGBoosterSaveModel()
BoosterHandle booster;
const char *model_path = "/path/of/model.json";
safe_xgboost(XGBoosterSaveModel(booster, model_path));

10. Load the model using XGBoosterLoadModel()

BoosterHandle booster;
const char *model_path = "/path/of/model.json";

// create booster handle first
safe_xgboost(XGBoosterCreate(NULL, 0, &booster));

// set the model parameters here

// load model
safe_xgboost(XGBoosterLoadModel(booster, model_path));

// predict the model here

11. Free all the internal structure used in your code using XGDMatrixFree() and XGBoosterFree(). This step is important to prevent memory leak.

safe_xgboost(XGDMatrixFree(dmatrix));
safe_xgboost(XGBoosterFree(booster));

1.4.17 Text Input Format of DMatrix

Here we will briefly describe the text input formats for XGBoost. However, for users with access to a supported language environment like Python or R, it’s recommended to use data parsers from that ecosystem instead. For instance, sklearn.datasets.load_svmlight_file().

Basic Input Format

XGBoost currently supports two text formats for ingesting data: LIBSVM and CSV. The rest of this document will describe the LIBSVM format. (See this Wikipedia article for a description of the CSV format.). Please be careful that, XGBoost does not understand file extensions, nor try to guess the file format, as there is no universal agreement upon file extension of LIBSVM or CSV. Instead it employs URI format for specifying the precise input file type. For example if you provide a csv file ./data.train.csv as input, XGBoost will blindly use the default LIBSVM parser to digest it and generate a parser error. Instead, users need to provide an URI in the form of train.csv?format=csv or train.csv?format=libsvm. For external memory input, the URI should of a form similar to train.csv?format=csv#dtrain.cache. See Data Interface and Using XGBoost External Memory Version also.

For training or predicting, XGBoost takes an instance file with the format as below:

Listing 18: train.txt

1 101:1.2 102:0.03
0 1:2.1 1001:300 10002:400
0 0:1.3 1:0.3
1 0:0.01 1:0.3
0 0:0.2 1:0.3

1.4. XGBoost Tutorials
Each line represent a single instance, and in the first line ‘1’ is the instance label, ‘101’ and ‘102’ are feature indices, ‘1.2’ and ‘0.03’ are feature values. In the binary classification case, ‘1’ is used to indicate positive samples, and ‘0’ is used to indicate negative samples. We also support probability values in [0,1] as label, to indicate the probability of the instance being positive.

**Auxiliary Files for Additional Information**

*Note: all information below is applicable only to single-node version of the package.* If you’d like to perform distributed training with multiple nodes, skip to the section *Embedding additional information inside LIBSVM file.*

**Group Input Format**

For **ranking task**, XGBoost supports the group input format. In ranking task, instances are categorized into *query groups* in real world scenarios. For example, in the learning to rank web pages scenario, the web page instances are grouped by their queries. XGBoost requires an file that indicates the group information. For example, if the instance file is the `train.txt` shown above, the group file should be named `train.txt.group` and be of the following format:

```
Listing 19: train.txt.group

2
3
```

This means that, the data set contains 5 instances, and the first two instances are in a group and the other three are in another group. The numbers in the group file are actually indicating the number of instances in each group in the instance file in order. At the time of configuration, you do not have to indicate the path of the group file. If the instance file name is `xxx`, XGBoost will check whether there is a file named `xxx.group` in the same directory.

**Instance Weight File**

Instances in the training data may be assigned weights to differentiate relative importance among them. For example, if we provide an instance weight file for the `train.txt` file in the example as below:

```
Listing 20: train.txt.weight

1 0.5
0.5
1
0.5
```

It means that XGBoost will emphasize more on the first and fourth instance (i.e. the positive instances) while training. The configuration is similar to configuring the group information. If the instance file name is `xxx`, XGBoost will look for a file named `xxx.weight` in the same directory. If the file exists, the instance weights will be extracted and used at the time of training.

**Note**

**Binary buffer format and instance weights**

If you choose to save the training data as a binary buffer (using `save_binary()`), keep in mind that the resulting binary buffer file will include the instance weights. To update the weights, use the `set_weight()` function.
Initial Margin File

XGBoost supports providing each instance an initial margin prediction. For example, if we have a initial prediction using logistic regression for `train.txt` file, we can create the following file:

```
Listing 21: train.txt.base_margin
-0.4
1.0
3.4
```

XGBoost will take these values as initial margin prediction and boost from that. An important note about base_margin is that it should be margin prediction before transformation, so if you are doing logistic loss, you will need to put in value before logistic transformation. If you are using XGBoost predictor, use `pred_margin=1` to output margin values.

Embedding additional information inside LIBSVM file

This section is applicable to both single- and multiple-node settings.

Query ID Columns

This is most useful for ranking task, where the instances are grouped into query groups. You may embed query group ID for each instance in the LIBSVM file by adding a token of form `qid:xx` in each row:

```
Listing 22: train.txt
1 qid:1 101:1.2 102:0.03
0 qid:1 1:2.1 10001:300 10002:400
0 qid:2 0:1.3 1:0.3
1 qid:2 0:0.01 1:0.3
0 qid:3 0:0.2 1:0.3
1 qid:3 3:-0.1 10:-0.3
0 qid:3 6:0.2 10:0.15
```

Keep in mind the following restrictions:

- You are not allowed to specify query ID’s for some instances but not for others. Either every row is assigned query ID’s or none at all.
- The rows have to be sorted in ascending order by the query IDs. So, for instance, you may not have one row having large query ID than any of the following rows.

Instance weights

You may specify instance weights in the LIBSVM file by appending each instance label with the corresponding weight in the form of `label:[weight]`, as shown by the following example:

```
Listing 23: train.txt
1:1.0 101:1.2 102:0.03
0:0.5 1:2.1 10001:300 10002:400
0:0.5 0:1.3 1:0.3
```

(continues on next page)
where the negative instances are assigned half weights compared to the positive instances.

### 1.4.18 Notes on Parameter Tuning

Parameter tuning is a dark art in machine learning, the optimal parameters of a model can depend on many scenarios. So it is impossible to create a comprehensive guide for doing so.

This document tries to provide some guideline for parameters in XGBoost.

**Understanding Bias-Variance Tradeoff**

If you take a machine learning or statistics course, this is likely to be one of the most important concepts. When we allow the model to get more complicated (e.g. more depth), the model has better ability to fit the training data, resulting in a less biased model. However, such complicated model requires more data to fit.

Most of parameters in XGBoost are about bias variance tradeoff. The best model should trade the model complexity with its predictive power carefully. *Parameters Documentation* will tell you whether each parameter will make the model more conservative or not. This can be used to help you turn the knob between complicated model and simple model.

**Control Overfitting**

When you observe high training accuracy, but low test accuracy, it is likely that you encountered overfitting problem.

There are in general two ways that you can control overfitting in XGBoost:

- The first way is to directly control model complexity.
  - This includes `max_depth`, `min_child_weight` and `gamma`.
- The second way is to add randomness to make training robust to noise.
  - This includes `subsample` and `colsample_bytree`.
  - You can also reduce stepsize `eta`. Remember to increase `num_round` when you do so.

**Handle Imbalanced Dataset**

For common cases such as ads clickthrough log, the dataset is extremely imbalanced. This can affect the training of XGBoost model, and there are two ways to improve it.

- If you care only about the overall performance metric (AUC) of your prediction
  - Balance the positive and negative weights via `scale_pos_weight`
  - Use AUC for evaluation
- If you care about predicting the right probability
  - In such a case, you cannot re-balance the dataset
  - Set parameter `max_delta_step` to a finite number (say 1) to help convergence
Reducing Memory Usage

If you are using a HPO library like `sklearn.model_selection.GridSearchCV`, please control the number of threads it can use. It’s best to let XGBoost run in parallel instead of asking `GridSearchCV` to run multiple experiments at the same time. For instance, creating a fold of data for cross validation can consume a significant amount of memory:

```python
# This creates a copy of dataset. X and X_train are both in memory at the same time.
# This happens for every thread at the same time if you run `GridSearchCV` with
# `n_jobs` larger than 1
X_train, X_test, y_train, y_test = train_test_split(X, y)
```

```python
df = pd.DataFrame()
# This creates a new copy of the dataframe, even if you specify the inplace parameter
new_df = df.drop(...)
```

```python
array = np.array(...)
# This may or may not make a copy of the data, depending on the type of the data
array.astype(np.float32)
```

```python
# np by default uses double, do you actually need it?
array = np.array(...)
```

You can find some more specific memory reduction practices scattered through the documents. For instance: *Distributed XGBoost with Dask, XGBoost GPU Support*. However, before going into these, being conscious about making data copies is a good starting point. It usually consumes a lot more memory than people expect.

### 1.4.19 Custom Objective and Evaluation Metric

**Contents**

- Overview
- Customized Objective Function
- Customized Metric Function
- Reverse Link Function
- Scikit-Learn Interface
Overview

XGBoost is designed to be an extensible library. One way to extend it is by providing our own objective function for training and corresponding metric for performance monitoring. This document introduces implementing a customized elementwise evaluation metric and objective for XGBoost. Although the introduction uses Python for demonstration, the concepts should be readily applicable to other language bindings.

Note

- The ranking task does not support customized functions.
- Breaking change was made in XGBoost 1.6.

See also the advanced usage example for more information about limitations and workarounds for more complex objectives: Advanced Usage of Custom Objectives

In the following two sections, we will provide a step by step walk through of implementing the Squared Log Error (SLE) objective function:

\[
\frac{1}{2} \left[ \log(\text{pred} + 1) - \log(\text{label} + 1) \right]^2
\]

and its default metric Root Mean Squared Log Error (RMSLE):

\[
\sqrt{\frac{1}{N} \left[ \log(\text{pred} + 1) - \log(\text{label} + 1) \right]^2}
\]

Although XGBoost has native support for said functions, using it for demonstration provides us the opportunity of comparing the result from our own implementation and the one from XGBoost internal for learning purposes. After finishing this tutorial, we should be able to provide our own functions for rapid experiments. And at the end, we will provide some notes on non-identity link function along with examples of using custom metric and objective with the scikit-learn interface.

If we compute the gradient of said objective function:

\[
g = \frac{\partial \text{objective}}{\partial \text{pred}} = \frac{\log(\text{pred} + 1) - \log(\text{label} + 1)}{\text{pred} + 1}
\]

As well as the hessian (the second derivative of the objective):

\[
h = \frac{\partial^2 \text{objective}}{\partial \text{pred}^2} = \frac{- \log(\text{pred} + 1) + \log(\text{label} + 1) + 1}{(\text{pred} + 1)^2}
\]

Customized Objective Function

During model training, the objective function plays an important role: provide gradient information, both first and second order gradient, based on model predictions and observed data labels (or targets). Therefore, a valid objective function should accept two inputs, namely prediction and labels. For implementing SLE, we define:

```python
import numpy as np
import xgboost as xgb
from typing import Tuple

def gradient(predt: np.ndarray, dtrain: xgb.DMatrix) -> np.ndarray:
    """Compute the gradient squared log error."""

(continues on next page)```
y = dtrain.get_label()
return (np.log1p(predt) - np.log1p(y)) / (predt + 1)

def hessian(predt: np.ndarray, dtrain: xgb.DMatrix) -> np.ndarray:
    """Compute the hessian for squared log error."""
    y = dtrain.get_label()
    return ((-np.log1p(predt) + np.log1p(y) + 1) / np.power(predt + 1, 2))

def squared_log(predt: np.ndarray, dtrain: xgb.DMatrix) -> Tuple[np.ndarray, np.ndarray]:
    """Squared Log Error objective. A simplified version for RMSLE used as objective function."
    predt[predt < -1] = -1 + 1e-6
    grad = gradient(predt, dtrain)
    hess = hessian(predt, dtrain)
    return grad, hess

In the above code snippet, squared_log is the objective function we want. It accepts a numpy array predt as model prediction, and the training DMatrix for obtaining required information, including labels and weights (not used here). This objective is then used as a callback function for XGBoost during training by passing it as an argument to xgb.train:

```python
xgb.train({'tree_method': 'hist', 'seed': 1994},  # any other tree method is fine.
        dtrain=dtrain,
        num_boost_round=10,
        obj=squared_log)
```

Notice that in our definition of the objective, whether we subtract the labels from the prediction or the other way around is important. If you find the training error goes up instead of down, this might be the reason.

**Customized Metric Function**

So after having a customized objective, we might also need a corresponding metric to monitor our model’s performance. As mentioned above, the default metric for SLE is RMSLE. Similarly we define another callback like function as the new metric:

```python
def rmsle(predt: np.ndarray, dtrain: xgb.DMatrix) -> Tuple[str, float]:
    """Root mean squared log error metric.""
    y = dtrain.get_label()
    predt[predt < -1] = -1 + 1e-6
    elements = np.power(np.log1p(y) - np.log1p(predt), 2)
    return 'PyRMSLE', float(np.sqrt(np.sum(elements) / len(y)))
```

Since we are demonstrating in Python, the metric or objective need not be a function, any callable object should suffice. Similar to the objective function, our metric also accepts predt and dtrain as inputs, but returns the name of the metric itself and a floating point value as the result. After passing it into XGBoost as argument of custom_metric parameter:

```python
xgb.train({'tree_method': 'hist', 'seed': 1994,
           'disable_default_eval_metric': 1},
        dtrain=dtrain,
        eval_metric=rmsle)
```
num_boost_round=10,
obj=squared_log,
custom_metric=rmsle,
evals=[(dtrain, 'dtrain'), (dtest, 'dtest')],
evals_result=results)

We will be able to see XGBoost printing something like:

[0] dtrain-PyRMSLE:1.37153 dtest-PyRMSLE:1.31487
[1] dtrain-PyRMSLE:1.26619 dtest-PyRMSLE:1.20899
[3] dtrain-PyRMSLE:1.09836 dtest-PyRMSLE:1.03871
[4] dtrain-PyRMSLE:1.03557 dtest-PyRMSLE:0.977186
[5] dtrain-PyRMSLE:0.985783 dtest-PyRMSLE:0.93057
...

Notice that the parameter disable_default_eval_metric is used to suppress the default metric in XGBoost.

For fully reproducible source code and comparison plots, see Demo for defining a custom regression objective and metric.

Reverse Link Function

When using built-in objective, the raw prediction is transformed according to the objective function. When a custom objective is provided XGBoost doesn’t know its link function so the user is responsible for making the transformation for both objective and custom evaluation metric. For objective with identity link like squared error this is trivial, but for other link functions like log link or inverse link the difference is significant.

For the Python package, the behaviour of prediction can be controlled by the output_margin parameter in predict function. When using the custom_metric parameter without a custom objective, the metric function will receive transformed prediction since the objective is defined by XGBoost. However, when the custom objective is also provided along with that metric, then both the objective and custom metric will receive raw prediction. The following example provides a comparison between two different behavior with a multi-class classification model. Firstly we define 2 different Python metric functions implementing the same underlying metric for comparison, merror_with_transform is used when custom objective is also used, otherwise the simpler merror is preferred since XGBoost can perform the transformation itself.

```python
import xgboost as xgb
import numpy as np
def merror_with_transform(predt: np.ndarray, dtrain: xgb.DMatrix):
    """Used when custom objective is supplied."""
    y = dtrain.get_label()
    n_classes = predt.size // y.shape[0]
    # Like custom objective, the predt is untransformed leaf weight when custom objective is provided.

    # With the use of `custom_metric` parameter in train function, custom metric receives raw input only when custom objective is also being used. Otherwise custom metric will receive transformed prediction.
    assert predt.shape == (d_train.num_row(), n_classes)
    out = np.zeros(dtrain.num_row())
    for r in range(predt.shape[0]):
```

(continues on next page)
The above function is only needed when we want to use custom objective and XGBoost doesn’t know how to transform the prediction. The normal implementation for multi-class error function is:

```python
def merror(predt: np.ndarray, dtrain: xgb.DMatrix):
    """Used when there's no custom objective."""
    # No need to do transform, XGBoost handles it internally.
    errors = np.zeros(dtrain.num_row())
    errors[y != out] = 1.0
    return 'PyMError', np.sum(errors) / dtrain.num_row()
```

Next we need the custom softprob objective:

```python
def softprob_obj(predt: np.ndarray, data: xgb.DMatrix):
    """Loss function. Computing the gradient and approximated hessian (diagonal).
    Reimplements the 'multi:softprob' inside XGBoost.
    """
    # Full implementation is available in the Python demo script linked below
    ...
    return grad, hess
```

Lastly we can train the model using `obj` and `custom_metric` parameters:

```python
Xy = xgb.DMatrix(X, y)
booster = xgb.train(
    {
    "num_class": kClasses,
    "disable_default_eval_metric": True,
    m,
    num_boost_round=kRounds,
    obj=softprob_obj,
    custom_metric=merror_with_transform,
    evals_result=custom_results,
    evals=[(m, "train")],
    }
)
```

Or if you don’t need the custom objective and just want to supply a metric that’s not available in XGBoost:

```python
booster = xgb.train(
    {
    "num_class": kClasses,
    "disable_default_eval_metric": True,
    "objective": "multi:softmax",
    },
    m,
)
```
We use multi:softmax to illustrate the differences of transformed prediction. With softprob the output prediction array has shape \((n_{\text{samples}}, n_{\text{classes}})\) while for softmax it's \((n_{\text{samples}}, )\). A demo for multi-class objective function is also available at Demo for creating customized multi-class objective function. Also, see Intercept for some more explanation.

**Scikit-Learn Interface**

The scikit-learn interface of XGBoost has some utilities to improve the integration with standard scikit-learn functions. For instance, after XGBoost 1.6.0 users can use the cost function (not scoring functions) from scikit-learn out of the box:

```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

Also, for custom objective function, users can define the objective without having to access DMatrix:

```python
def softprob_obj(labels: np.ndarray, predt: np.ndarray) -> Tuple[np.ndarray, np.ndarray]:
    rows = labels.shape[0]
    classes = predt.shape[1]
    grad = np.zeros((rows, classes), dtype=float)
    hess = np.zeros((rows, classes), dtype=float)
    eps = 1e-6
    for r in range(predt.shape[0]):
        target = labels[r]
        p = softmax(predt[r, :])
        for c in range(predt.shape[1]):
            g = p[c] - 1.0 if c == target else p[c]
            h = max((2.0 * p[c] * (1.0 - p[c])).item(), eps)
            grad[r, c] = g
            hess[r, c] = h
    grad = grad.reshape((rows * classes, 1))
    hess = hess.reshape((rows * classes, 1))
    return grad, hess

clf = xgb.XGBClassifier(tree_method="hist", objective=softprob_obj)
```
1.4.20 Advanced Usage of Custom Objectives

Overview

XGBoost allows optimizing custom user-defined functions based on gradients and Hessians provided by the user for the desired objective function.

In order for a custom objective to work as intended:

- The function to optimize must be smooth and twice differentiable.
- The function must be additive with respect to rows / observations, such as a likelihood function with i.i.d. assumptions.
- The range of the scores for the function must be unbounded (i.e. it should not work exclusively with positive numbers, for example).
- The function must be convex. Note that, if the Hessian has negative values, they will be clipped, which will likely result in a model that does not fit the function well.
- For multi-output objectives, there should not be dependencies between different targets (i.e. Hessian should be diagonal for each row).

Some of these limitations can nevertheless be worked around by foregoing the true Hessian of the function, using something else instead such as an approximation with better properties - convergence might be slower when not using the true Hessian of a function, but many theoretical guarantees should still hold and result in usable models. For example, XGBoost’s internal implementation of multinomial logistic regression uses an upper bound on the Hessian with diagonal structure instead of the true Hessian which is a full square matrix for each row in the data.

This tutorial provides some suggestions for use-cases that do not perfectly fit the criteria outlined above, by showing how to solve a Dirichlet regression parameterized by concentrations.

A Dirichlet regression model poses certain challenges for XGBoost:

- Concentration parameters must be positive. An easy way to achieve this is by applying an ‘exp’ transform on raw unbounded values, but in such case the objective becomes non-convex. Furthermore, note that this function is not in the exponential family, unlike typical distributions used for GLM models.
- The Hessian has dependencies between targets - that is, for a Dirichlet distribution with ‘k’ parameters, each row will have a full Hessian matrix of dimensions \([k, k]\).
- An optimal intercept for this type of model would involve a vector of values rather than the same value for every target.

In order to use this type of model as a custom objective:

- It’s possible to use the expected Hessian (a.k.a. the Fisher information matrix or expected information) instead of the true Hessian. The expected Hessian is always positive semi-definite for an additive likelihood, even if the true Hessian isn’t.
• It’s possible to use an upper bound on the expected Hessian with a diagonal structure, such that a second-order approximation under this diagonal bound would always yield greater or equal function values than under the non-diagonal expected Hessian.

• Since the base_score parameter that XGBoost uses for an intercept is limited to a scalar, one can use the base_margin functionality instead, but note that using it requires a bit more effort.

**Dirichlet Regression Formulae**

The Dirichlet distribution is a generalization of the Beta distribution to multiple dimensions. It models proportions data in which the values sum to 1, and is typically used as part of composite models (e.g. Dirichlet-multinomial) or as a prior in Bayesian models, but it also can be used on its own for proportions data for example.

Its likelihood for a given observation with values \( y \) and a given prediction \( x \) is given as follows:

\[
L(y|x) = \frac{1}{\beta(x)} \prod_{i=1}^{k} y_i^{x_i-1}
\]

Where:

\[
\beta(x) = \frac{\prod_{i=1}^{k} \Gamma(x_i)}{\Gamma(\sum_{i=1}^{k} x_i)}
\]

In this case, we want to optimize the negative of the log-likelihood summed across rows. The resulting function, gradient and Hessian could be implemented as follows:

Listing 24: Python

```python
import numpy as np
from scipy.special import loggamma, psi as digamma, polygamma

trigamma = lambda x: polygamma(1, x)

def dirichlet_fun(pred: np.ndarray, Y: np.ndarray) -> float:
    epred = np.exp(pred)
    sum_epred = np.sum(epred, axis=1, keepdims=True)
    return (loggamma(epred).sum() - loggamma(sum_epred).sum() - np.sum(np.log(Y) * (epred - 1))

def dirichlet_grad(pred: np.ndarray, Y: np.ndarray) -> np.ndarray:
    epred = np.exp(pred)
    return epred * (digamma(epred) - digamma(np.sum(epred, axis=1, keepdims=True)) - np.log(Y))

def dirichlet_hess(pred: np.ndarray, Y: np.ndarray) -> np.ndarray:
    epred = np.exp(pred)
    grad = dirichlet_grad(pred, Y)
    k = Y.shape[1]
    H = np.empty((np.prod(pred.shape), k, k))
    for row in range(np.prod(pred.shape)):
        H[row, :, :] = (
```

(continues on next page)
trigamma(epred[\text{row}].sum()) * np.outer(epred[\text{row}], epred[\text{row}])
+ np.diag(grad[\text{row}] + trigamma(epred[\text{row}]) * epred[\text{row}] ** 2)

return H

Listing 25: R

softmax <- function(x) {
  max.x <- max(x)
  e <- exp(x - max.x)
  return(e / sum(e))
}

dirichlet.fun <- function(pred, y) {
  epred <- exp(pred)
  sum_epred <- rowSums(epred)
  return(
    sum(lgamma(epred))
    - sum(lgamma(sum_epred))
    - sum(log(y) * (epred - 1))
  )
}

dirichlet.grad <- function(pred, y) {
  epred <- exp(pred)
  return(
    epred * (digamma(epred)
              - digamma(rowSums(epred))
              - log(y))
  )
}

dirichlet.hess <- function(pred, y) {
  epred <- exp(pred)
  grad <- dirichlet.grad(pred, y)
  k <- ncol(y)
  H <- array(dim = c(nrow(y), k, k))
  for (row in seq_len(nrow(y))) {
    H[row, , ] <- (
      - trigamma(sum(epred[row,])) * tcrossprod(epred[row,])
      + diag(grad[row,] + trigamma(epred[row,]) * epred[row,]^2)
    )
  }
  return(H)
}

Convince yourself that the implementation is correct:
Listing 26: Python

```python
from math import isclose
from scipy import stats
from scipy.optimize import check_grad
from scipy.special import softmax

def gen_random_dirichlet(rng: np.random.Generator, m: int, k: int):
    alpha = np.exp(rng.standard_normal(size=k))
    return rng.dirichlet(alpha, size=m)

def test_dirichlet_fun_grad_hess():
    k = 3
    m = 10
    rng = np.random.default_rng(seed=123)
    Y = gen_random_dirichlet(rng, m, k)
    x0 = rng.standard_normal(size=k)
    for row in range(Y.shape[0]):
        fun_row = dirichlet_fun(x0.reshape((1,-1)), Y[row])
        ref_logpdf = stats.dirichlet.logpdf(
            Y[row] / Y[row].sum(), # <- avoid roundoff error
            np.exp(x0),
        )
        assert isclose(fun_row, -ref_logpdf)

        gdiff = check_grad(
            lambda pred: dirichlet_fun(pred.reshape((1,-1)), Y[row]),
            lambda pred: dirichlet_grad(pred.reshape((1,-1)), Y[row]),
            x0
        )
        assert gdiff <= 1e-6

        H_numeric = np.empty((k,k))
        eps = 1e-7
        for ii in range(k):
            x0_plus_eps = x0.reshape((1,-1)).copy()
            x0_plus_eps[0,ii] += eps
            for jj in range(k):
                H_numeric[ii, jj] = (dirichlet_grad(x0_plus_eps, Y[row])[0][jj] - dirichlet_grad(x0.reshape((1,-1)), Y[row])[0][jj]) / eps
        H = dirichlet_hess(x0.reshape((1,-1)), Y[row])[0]
        np.testing.assert_almost_equal(H, H_numeric, decimal=6)

    test_dirichlet_fun_grad_hess()
```

Listing 27: R

```r
library(DirichletReg)
library(testthat)

test_that("dirichlet formulae", {
```
```r
k <- 3L
m <- 10L
set.seed(123)
alpha <- exp(rnorm(k))
y <- rdirichlet(m, alpha)
x0 <- rnorm(k)
for (row in seq_len(m)) {
  logpdf <- dirichlet.fun(matrix(x0, nrow=1), y[row,,drop=F])
  ref_logpdf <- ddirichlet(y[row,,drop=F], exp(x0), log = T)
  expect_equal(logpdf, -ref_logpdf)
  eps <- 1e-7
  grad_num <- numeric(k)
  for (col in seq_len(k)) {
    xplus <- x0
    xplus[col] <- x0[col] + eps
    grad_num[col] <- (
      dirichlet.fun(matrix(xplus, nrow=1), y[row,,drop=F])
      - dirichlet.fun(matrix(x0, nrow=1), y[row,,drop=F])
      ) / eps
  }
  grad <- dirichlet.grad(matrix(x0, nrow=1), y[row,,drop=F])
  expect_equal(grad |> as.vector(), grad_num, tolerance=1e-6)
  H_numeric <- array(dim=c(k, k))
  for (ii in seq_len(k)) {
    xplus <- x0
    xplus[ii] <- x0[ii] + eps
    for (jj in seq_len(k)) {
      H_numeric[ii, jj] <- (
        dirichlet.grad(matrix(xplus, nrow=1), y[row,,drop=F])[1, jj]
        - grad[1L, jj]
      ) / eps
    }
  }
  H <- dirichlet.hess(matrix(xplus, nrow=1), y[row,,drop=F])
  expect_equal(H[1,,], H_numeric, tolerance=1e-6)
}
```
Dirichlet Regression as Objective Function

As mentioned earlier, the Hessian of this function is problematic for XGBoost: it can have a negative determinant, and might even have negative values in the diagonal, which is problematic for optimization methods - in XGBoost, those values would be clipped and the resulting model might not end up producing sensible predictions.

A potential workaround is to use the expected Hessian instead - that is, the expected outer product of the gradient if the response variable were distributed according to what is predicted. See the Wikipedia article for more information:

https://en.wikipedia.org/wiki/Fisher_information

In general, for objective functions in the exponential family, this is easy to obtain from the gradient of the link function and the variance of the probability distribution, but for other functions in general, it might involve other types of calculations (e.g. covariances and covariances of logarithms for Dirichlet).

It nevertheless results in a form very similar to the Hessian. One can also see from the differences here that, at an optimal point (gradient being zero), the expected and true Hessian for Dirichlet will match, which is a nice property for optimization (i.e. the Hessian will be positive at a stationary point, which means it will be a minimum rather than a maximum or saddle point).

Listing 28: Python

```python
def dirichlet_expected_hess(pred: np.ndarray) -> np.ndarray:
    epred = np.exp(pred)
    k = pred.shape[1]
    Ehess = np.empty((pred.shape[0], k, k))
    for row in range(pred.shape[0]):
        Ehess[row, :, :] = (- trgamma(epred[row].sum()) * np.outer(epred[row], epred[row])
                            + np.diag(trgamma(epred[row]) * epred[row] ** 2))
    return Ehess

def test_dirichlet_expected_hess():
    k = 3
    rng = np.random.default_rng(seed=123)
    x0 = rng.standard_normal(size=k)
    y_sample = rng.dirichlet(np.exp(x0), size=5_000_000)
    x_broadcast = np.broadcast_to(x0, (y_sample.shape[0], k))
    g_sample = dirichlet_grad(x_broadcast, y_sample)
    ref = (g_sample.T @ g_sample) / y_sample.shape[0]
    Ehess = dirichlet_expected_hess(x0.reshape((1,-1)))[0]
    np.testing.assert_almost_equal(Ehess, ref, decimal=2)

test_dirichlet_expected_hess()
```

Listing 29: R

```r
dirichlet.expected.hess <- function(pred) {
    epred <- exp(pred)
    k <- ncol(pred)
    H <- array(dim = c(nrow(pred), k, k))
    for (row in seq_len(nrow(pred))) {
        H[row, , ] <- (- trgamma(sum(epred[row,])) * tcrossprod(epred[row,])
                        + diag(trgamma(epred[row,]) * epred[row,]^2))
    }
}
```
But note that this is still not usable for XGBoost, since the expected Hessian, just like the true Hessian, has shape \([nrows, k, k]\) while XGBoost requires something with shape \([k, k]\).

One may use the diagonal of the expected Hessian for each row, but it’s possible to do better: one can use instead an upper bound with diagonal structure, since it should lead to better convergence properties, just like for other Hessian-based optimization methods.

In the absence of any obvious way of obtaining an upper bound, a possibility here is to construct such a bound numerically based directly on the definition of a diagonally dominant matrix:

That is: take the absolute value of the expected Hessian for each row of the data, and sum by rows of the \([k, k]\)-shaped Hessian for that row in the data:

Listing 30: Python

```python
def dirichlet_diag_upper_bound_expected_hess(pred: np.ndarray, Y: np.ndarray) -> np.ndarray:
    Ehess = dirichlet_expected_hess(pred)
    diag_bound_Ehess = np.empty((pred.shape[0], Y.shape[1]))
    for row in range(pred.shape[0]):
        diag_bound_Ehess[row, :] = np.abs(Ehess[row, :, :]).sum(axis=1)
    return diag_bound_Ehess
```

Listing 31: R

```r
dirichlet.diag.upper.bound.expected.hess <- function(pred, y) {
    Ehess <- dirichlet.expected.hess(pred)
    diag_bound_Ehess <- array(dim=dim(pred))
    for (row in seq_len(nrow(pred))) {
        diag_bound_Ehess[row, ] <- abs(Ehess[row, ,]) |> rowSums()
    }
    return(diag_bound_Ehess)
}
```
With all these pieces in place, one can now frame this model into the format required for XGBoost’s custom objectives:

Listing 32: Python

```python
import xgboost as xgb
from typing import Tuple

def dirichlet_xgb_objective(
    pred: np.ndarray, dtrain: xgb.DMatrix
) -> Tuple[np.ndarray, np.ndarray]:
    Y = dtrain.get_label().reshape(pred.shape)
    return
        dirichlet_grad(pred, Y),
        dirichlet_diag_upper_bound_expected_hess(pred, Y),
)
```

Listing 33: R

```r
library(xgboost)
dirichlet.xgb.objective <- function(pred, dtrain) {
    y <- getinfo(dtrain, "label")
    return(
        list(
            grad = dirichlet.grad(pred, y),
            hess = dirichlet.diag.upper.bound.expected.hess(pred, y)
        )
    )
}
```

And for an evaluation metric monitoring based on the Dirichlet log-likelihood:

Listing 34: Python

```python
def dirichlet_eval_metric(
    pred: np.ndarray, dtrain: xgb.DMatrix
) -> Tuple[str, float]:
    Y = dtrain.get_label().reshape(pred.shape)
    return "dirichlet_ll", dirichlet_fun(pred, Y)
```

Listing 35: R

```r
dirichlet.eval.metric <- function(pred, dtrain) {
    y <- getinfo(dtrain, "label")
    ll <- dirichlet.fun(pred, y)
    return(
        list(
            metric = "dirichlet_ll",
        )
    )
```

(continues on next page)
Practical Example

A good source for test datasets for proportions data is the R package DirichletReg:

https://cran.r-project.org/package=DirichletReg

For this example, we’ll now use the Arctic Lake dataset (Aitchison, J. (2003). The Statistical Analysis of Compositional Data. The Blackburn Press, Caldwell, NJ.), taken from the DirichletReg R package, which consists of 39 rows with one predictor variable ‘depth’ and a three-valued response variable denoting the sediment composition of the measurements in this arctic lake (sand, silt, clay).

The data:

```
Listing 36: Python

# depth
X = np.array([
    10.4, 11.7, 12.8, 13, 15.7, 16.3, 18, 18.7, 20.7, 22.1,
    22.4, 24.4, 25.8, 32.5, 33.6, 36.8, 37.8, 36.9, 42.2, 47,
    47.1, 48.4, 49.4, 49.5, 59.2, 60.1, 61.7, 62.4, 69.3, 73.6,
    74.4, 78.5, 82.9, 87.7, 88.1, 90.4, 90.6, 97.7, 103.7,
]).reshape((-1, 1))

# sand, silt, clay
Y = np.array([
    [0.775, 0.195, 0.03], [0.719, 0.249, 0.032], [0.507, 0.361, 0.132],
    [0.522, 0.409, 0.066], [0.7, 0.265, 0.035], [0.665, 0.322, 0.013],
    [0.431, 0.553, 0.016], [0.534, 0.368, 0.098], [0.155, 0.544, 0.301],
    [0.317, 0.415, 0.268], [0.657, 0.278, 0.065], [0.704, 0.29, 0.006],
    [0.174, 0.536, 0.29], [0.106, 0.698, 0.196], [0.382, 0.431, 0.187],
    [0.108, 0.527, 0.365], [0.184, 0.507, 0.309], [0.046, 0.474, 0.48],
    [0.156, 0.504, 0.34], [0.319, 0.451, 0.23], [0.095, 0.535, 0.37],
    [0.171, 0.48, 0.349], [0.105, 0.554, 0.341], [0.048, 0.547, 0.41],
    [0.026, 0.452, 0.522], [0.114, 0.527, 0.359], [0.067, 0.469, 0.464],
    [0.069, 0.497, 0.434], [0.04, 0.449, 0.511], [0.074, 0.516, 0.409],
    [0.048, 0.495, 0.457], [0.045, 0.485, 0.47], [0.066, 0.521, 0.413],
    [0.067, 0.473, 0.459], [0.074, 0.456, 0.469], [0.06, 0.489, 0.451],
    [0.063, 0.538, 0.399], [0.025, 0.48, 0.495], [0.02, 0.478, 0.502],
])
```

Listing 37: R

```
data("ArcticLake", package="DirichletReg")
x <- ArcticLake[, c("depth"), drop=F]
y <- ArcticLake[, c("sand", "silt", "clay")]%>%as.matrix()
```

Fitting an XGBoost model and making predictions:
Listing 38: Python

```python
from typing import Dict, List
dtrain = xgb.DMatrix(X, label=Y)
results: Dict[str, Dict[str, List[float]]] = {}
booster = xgb.train(params={
    "tree_method": "hist",
    "num_target": Y.shape[1],
    "base_score": 0,
    "disable_default_eval_metric": True,
    "max_depth": 3,
    "seed": 123,
},
dtrain=dtrain,
num_boost_round=10,
obj=dirichlet_xgb_objective,
evals=[(dtrain, "Train")],
evals_result=results,
custom_metric=dirichlet_eval_metric,
)
yhat = softmax(booster.inplace_predict(X), axis=1)
```

Listing 39: R

```r
dtrain <- xgb.DMatrix(x, y)
booster <- xgb.train(params = list(
    tree_method="hist",
    num_target=ncol(y),
    base_score=0,
    disable_default_eval_metric=TRUE,
    max_depth=3,
    seed=123
  ),
data = dtrain,
nrounds = 10,
obj = dirichlet.xgb.objective,
evals = list(Train=dtrain),
eval_metric = dirichlet.eval.metric
)
raw.pred <- predict(booster, x, reshape=TRUE)
yhat <- apply(raw.pred, 1, softmax) |> t()
```

Should produce an evaluation log as follows (note: the function is decreasing as expected - but unlike other objectives, the minimum value here can reach below zero):

```
[0] Train-dirichlet_ll:-40.25009
[1] Train-dirichlet_ll:-47.69122
[2] Train-dirichlet_ll:-52.64620
[3] Train-dirichlet_ll:-56.36977
(continues on next page)
```
One can confirm that the obtained yhat resembles the actual concentrations to a large degree, beyond what would be expected from random predictions by a simple look at both yhat and Y.

For better results, one might want to add an intercept. XGBoost only allows using scalars for intercepts, but for a vector-valued model, the optimal intercept should also have vector form.

This can be done by supplying base_margin instead - unlike the intercept, one must specifically supply values for every row here, and said base_margin must be supplied again at the moment of making predictions (i.e. does not get added automatically like base_score does).

For the case of a Dirichlet model, the optimal intercept can be obtained efficiently using a general solver (e.g. SciPy’s Newton solver) with dedicated likelihood, gradient and Hessian functions for just the intercept part. Further, note that if one frames it instead as bounded optimization without applying ‘exp’ transform to the concentrations, it becomes instead a convex problem, for which the true Hessian can be used without issues in other classes of solvers.

For simplicity, this example will nevertheless reuse the same likelihood and gradient functions that were defined earlier alongside with SciPy’s / R’s L-BFGS solver to obtain the optimal vector-valued intercept:

**Listing 40: Python**

```python
from scipy.optimize import minimize

def get_optimal_intercepts(Y: np.ndarray) -> np.ndarray:
    k = Y.shape[1]
    res = minimize(
        fun=lambda pred: dirichlet_fun(
            np.broadcast_to(pred, (Y.shape[0], k)), Y)
        ,
        x0=np.zeros(k),
        jac=lambda pred: dirichlet_grad(
            np.broadcast_to(pred, (Y.shape[0], k)), Y)
        .sum(axis=0)
    )
    return res["x"]

intercepts = get_optimal_intercepts(Y)
```

**Listing 41: R**

```r
get.optimal.intercepts <- function(y) {
    k <- ncol(y)
    broadcast.vec <- function(x) rep(x, nrow(y)) | matrix(ncol=k, byrow=T)
    res <- optim(
        par = numeric(k),
        fn = function(x) dirichlet.fun(broadcast.vec(x), y),
        gr = function(x) dirichlet.grad(broadcast.vec(x), y) | colSums()
        ,
        method = "L-BFGS-B"
    )
    return(res["x"])
}
```

(continued on next page)
Now fitting a model again, this time with the intercept:

Listing 42: Python

```python
base_margin = np.broadcast_to(intercepts, Y.shape)
dtrain_w_intercept = xgb.DMatrix(X, label=Y, base_margin=base_margin)
results: Dict[str, Dict[str, List[float]]] = {}
booster = xgb.train(params={
    "tree_method": "hist",
    "num_target": Y.shape[1],
    "base_score": 0,
    "disable_default_eval_metric": True,
    "max_depth": 3,
    "seed": 123,
},
    dtrain=dtrain_w_intercept,
    num_boost_round=10,
    obj=dirichlet_xgb_objective,
    evals=[(dtrain, "Train")],
    evals_result=results,
    custom_metric=dirichlet_eval_metric,
)
yhat = softmax(
    booster.predict(
        xgb.DMatrix(X, base_margin=base_margin)
    ),
    axis=1
)
```

Listing 43: R

```r
base.margin <- rep(intercepts, nrow(y)) |> matrix(nrow=nrow(y), byrow=T)
dtrain <- xgb.DMatrix(x, y, base_margin=base.margin)
booster <- xgb.train(
    params = list(
        tree_method="hist",
        num_target=ncol(y),
        base_score=0,
        disable_default_eval_metric=TRUE,
        max_depth=3,
        seed=123
    ),
    data = dtrain,
    nrounds = 10,
    obj = dirichlet.xgb.objective,
    evals = list(Train=dtrain),
)```
eval_metric = dirichlet.eval.metric

raw.pred <- predict(
    booster,
    x, 
    base_margin=base.margin, 
    reshape=TRUE
)

yhat <- apply(raw.pred, 1, softmax) |> t()

[0] Train-dirichlet_ll:-37.01861
[1] Train-dirichlet_ll:-42.86120
[2] Train-dirichlet_ll:-46.55133
[3] Train-dirichlet_ll:-49.15111
[4] Train-dirichlet_ll:-51.02638
[5] Train-dirichlet_ll:-52.53880
[6] Train-dirichlet_ll:-53.77409
[7] Train-dirichlet_ll:-54.88851
[8] Train-dirichlet_ll:-55.95961
[9] Train-dirichlet_ll:-56.95497

For this small example problem, predictions should be very similar between the two and the version without intercepts achieved a lower objective function in the training data (for the Python version at least), but for more serious usage with real-world data, one is likely to observe better results when adding the intercepts.

1.4.21 Intercept

Added in version 2.0.0.

Since 2.0.0, XGBoost supports estimating the model intercept (named base_score) automatically based on targets upon training. The behavior can be controlled by setting base_score to a constant value. The following snippet disables the automatic estimation:

```
import xgboost as xgb
reg = xgb.XGBRegressor()
reg.set_params(base_score=0.5)
```

In addition, here 0.5 represents the value after applying the inverse link function. See the end of the document for a description.

Other than the base_score, users can also provide global bias via the data field base_margin, which is a vector or a matrix depending on the task. With multi-output and multi-class, the base_margin is a matrix with size (n_samples, n_targets) or (n_samples, n_classes).

```
import xgboost as xgb
from sklearn.datasets import make_regression

X, y = make_regression()
reg = xgb.XGBRegressor()
reg.fit(X, y)
```
# Request for raw prediction
m = reg.predict(X, output_margin=True)

reg_1 = xgb.XGBRegressor()
# Feed the prediction into the next model
reg_1.fit(X, y, base_margin=m)
reg_1.predict(X, base_margin=m)

It specifies the bias for each sample and can be used for stacking an XGBoost model on top of other models, see Demo for boosting from prediction for a worked example. When base_margin is specified, it automatically overrides the base_score parameter. If you are stacking XGBoost models, then the usage should be relatively straightforward, with the previous model providing raw prediction and a new model using the prediction as bias. For more customized inputs, users need to take extra care of the link function. Let $F$ be the model and $g$ be the link function, since base_score is overridden when sample-specific base_margin is available, we will omit it here:

$$g(E[y_i]) = F(x_i)$$

When base margin $b$ is provided, it’s added to the raw model output $F$:

$$g(E[y_i]) = F(x_i) + b_i$$

and the output of the final model is:

$$g^{-1}(F(x_i) + b_i)$$

Using the gamma deviance objective reg:gamma as an example, which has a log link function, hence:

$$\ln (E[y_i]) = F(x_i) + b_i$$
$$E[y_i] = \exp (F(x_i) + b_i)$$

As a result, if you are feeding outputs from models like GLM with a corresponding objective function, make sure the outputs are not yet transformed by the inverse link (activation).

In the case of base_score (intercept), it can be accessed through save_config() after estimation. Unlike the base_margin, the returned value represents a value after applying inverse link. With logistic regression and the logit link function as an example, given the base_score as 0.5, $g(\text{intercept}) = \text{logit}(0.5) = 0$ is added to the raw model output:

$$E[y_i] = g^{-1}(F(x_i) + g(\text{intercept}))$$

and 0.5 is the same as base_score = $g^{-1}(0) = 0.5$. This is more intuitive if you remove the model and consider only the intercept, which is estimated before the model is fitted:

$$E[y] = g^{-1}(g(\text{intercept}))$$
$$E[y] = \text{intercept}$$

For some objectives like MAE, there are close solutions, while for others it’s estimated with one step Newton method.

## 1.4.22 Privacy Preserving Inference with Concrete ML

Concrete ML is a specialized library developed by Zama that allows the execution of machine learning models on encrypted data through Fully Homomorphic Encryption (FHE), thereby preserving data privacy.

To use models such as XGBClassifier, use the following import:
Performing Privacy Preserving Inference

Initialization of a XGBClassifier can be done as follows:

```python
classifier = XGBClassifier(n_bits=6, [other_hyperparameters])
```

where `n_bits` determines the precision of the input features. Note that a higher value of `n_bits` increases the precision of the input features and possibly the final model accuracy but also ends up with longer FHE execution time.

Other hyper-parameters that exist in xgboost library can be used.

Model Training and Compilation

As commonly used in scikit-learn like models, it can be trained with the `.fit()` method.

```python
classifier.fit(X_train, y_train)
```

After training, the model can be compiled with a calibration dataset, potentially a subset of the training data:

```python
classifier.compile(X_calibrate)
```

This calibration dataset, `X_calibrate`, is used in Concrete ML compute the precision (bit-width) of each intermediate value in the model. This is a necessary step to optimize the equivalent FHE circuit.

FHE Simulation and Execution

To verify model accuracy in encrypted computations, you can run an FHE simulation:

```python
predictions = classifier.predict(X_test, fhe="simulate")
```

This simulation can be used to evaluate the model. The resulting accuracy of this simulation step is representative of the actual FHE execution without having to pay the cost of an actual FHE execution.

When the model is ready, actual Fully Homomorphic Encryption execution can be performed:

```python
predictions = classifier.predict(X_test, fhe="execute")
```

Note that using FHE="execute" is a convenient way to assess the model in FHE, but for real deployment, functions to encrypt (on the client), run in FHE (on the server), and finally decrypt (on the client) have to be used for end-to-end privacy-preserving inferences.

Concrete ML provides a deployment API to facilitate this process, ensuring end-to-end privacy.

To go further in the deployment API you can read:

- the deployment documentation
- the deployment notebook
Parameter Tuning in Concrete ML

Concrete ML is compatible with standard scikit-learn pipelines such as GridSearchCV or any other hyper-parameter tuning techniques.

Examples and Demos

- Sentiment analysis (based on transformers + xgboost)
- XGBoost Classifier
- XGBoost Regressor

Conclusion

Concrete ML provides a framework for executing privacy-preserving inferences by leveraging Fully Homomorphic Encryption, allowing secure and private computations on encrypted data.

More information and examples are given in the Concrete ML documentation.

1.5 Frequently Asked Questions

This document contains frequently asked questions about XGBoost.

1.5.1 How to tune parameters

See Parameter Tuning Guide.

1.5.2 Description of the model

See Introduction to Boosted Trees.

1.5.3 I have a big dataset

XGBoost is designed to be memory efficient. Usually it can handle problems as long as the data fits into your memory. This usually means millions of instances.

If you are running out of memory, checkout the tutorial page for using distributed training with one of the many frameworks, or the external memory version for using external memory.
1.5.4 How to handle categorical feature?

Visit this tutorial for a walkthrough of categorical data handling and some worked examples.

1.5.5 Why not implement distributed XGBoost on top of X (Spark, Hadoop)?

The first fact we need to know is going distributed does not necessarily solve all the problems. Instead, it creates more problems such as more communication overhead and fault tolerance. The ultimate question will still come back to how to push the limit of each computation node and use less resources to complete the task (thus with less communication and chance of failure).

To achieve these, we decide to reuse the optimizations in the single node XGBoost and build the distributed version on top of it. The demand for communication in machine learning is rather simple, in the sense that we can depend on a limited set of APIs. Such design allows us to reuse most of the code, while being portable to major platforms such as Hadoop/Yarn, MPI, SGE. Most importantly, it pushes the limit of the computation resources we can use.

1.5.6 How can I port a model to my own system?

The model and data format of XGBoost are exchangeable, which means the model trained by one language can be loaded in another. This means you can train the model using R, while running prediction using Java or C++, which are more common in production systems. You can also train the model using distributed versions, and load them in from Python to do some interactive analysis. See Model IO for more information.

1.5.7 Do you support LambdaMART?

Yes, XGBoost implements LambdaMART. Checkout the objective section in parameters.

1.5.8 How to deal with missing values

XGBoost supports missing values by default. In tree algorithms, branch directions for missing values are learned during training. Note that the gblinear booster treats missing values as zeros.

When the missing parameter is specified, values in the input predictor that is equal to missing will be treated as missing and removed. By default it’s set to NaN.

1.5.9 Slightly different result between runs

This could happen, due to non-determinism in floating point summation order and multi-threading. Also, data partitioning changes by distributed framework can be an issue as well. Though the general accuracy will usually remain the same.
1.5.10 Why do I see different results with sparse and dense data?

“Sparse” elements are treated as if they were “missing” by the tree booster, and as zeros by the linear booster. However, if we convert the sparse matrix back to dense matrix, the sparse matrix might fill the missing entries with 0, which is a valid value for xgboost.

1.6 XGBoost GPU Support

This page contains information about GPU algorithms supported in XGBoost.

Note

CUDA 11.0, Compute Capability 5.0 required (See this list to look up compute capability of your GPU card.)

1.6.1 CUDA Accelerated Tree Construction Algorithms

Most of the algorithms in XGBoost including training, prediction and evaluation can be accelerated with CUDA-capable GPUs.

Usage

To enable GPU acceleration, specify the device parameter as cuda. In addition, the device ordinal (which GPU to use if you have multiple devices in the same node) can be specified using the cuda:<ordinal> syntax, where <ordinal> is an integer that represents the device ordinal. XGBoost defaults to 0 (the first device reported by CUDA runtime).

The GPU algorithms currently work with CLI, Python, R, and JVM packages. See Installation Guide for details.

Listing 44: Python example

```python
params = dict()
params[“device”] = “cuda”
params[“tree_method”] = “hist”
Xy = xgboost.QuantileDMatrix(X, y)
xgboost.train(params, Xy)
```

Listing 45: With the Scikit-Learn interface

```python
XGBRegressor(tree_method=“hist”, device=“cuda”)
```

GPU-Accelerated SHAP values

XGBoost makes use of GPU TreeShap as a backend for computing shap values when the GPU is used.

```python
booster.set_param({“device”: “cuda:0”})
shap_values = booster.predict(dtrain, pred_contribs=True)
shap_interaction_values = model.predict(dtrain, pred_interactions=True)
```

See Use GPU to speedup SHAP value computation for a worked example.
**Multi-node Multi-GPU Training**

XGBoost supports fully distributed GPU training using Dask, Spark and PySpark. For getting started with Dask see our tutorial *Distributed XGBoost with Dask* and worked examples *XGBoost Dask Feature Walkthrough*, also Python documentation *Dask API* for complete reference. For usage with Spark using Scala see *XGBoost4J-Spark-GPU Tutorial (version 1.6.1+)*. Lastly for distributed GPU training with PySpark, see *Distributed XGBoost with PySpark*.

**RMM integration**

XGBoost provides optional support for RMM integration. See *Using XGBoost with RAPIDS Memory Manager (RMM) plugin* for more info.

**Memory usage**

The following are some guidelines on the device memory usage of the hist tree method on GPU.

Memory inside xgboost training is generally allocated for two reasons - storing the dataset and working memory.

The dataset itself is stored on device in a compressed ELLPACK format. The ELLPACK format is a type of sparse matrix that stores elements with a constant row stride. This format is convenient for parallel computation when compared to CSR because the row index of each element is known directly from its address in memory. The disadvantage of the ELLPACK format is that it becomes less memory efficient if the maximum row length is significantly more than the average row length. Elements are quantised and stored as integers. These integers are compressed to a minimum bit length. Depending on the number of features, we usually don’t need the full range of a 32 bit integer to store elements and so compress this down. The compressed, quantised ELLPACK format will commonly use 1/4 the space of a CSR matrix stored in floating point.

Working memory is allocated inside the algorithm proportional to the number of rows to keep track of gradients, tree positions and other per row statistics. Memory is allocated for histogram bins proportional to the number of bins, number of features and nodes in the tree. For performance reasons we keep histograms in memory from previous nodes in the tree, when a certain threshold of memory usage is passed we stop doing this to conserve memory at some performance loss.

If you are getting out-of-memory errors on a big dataset, try the *xgboost.QuantileDMatrix* or *external memory version*. Note that when *external memory* is used for GPU hist, it’s best to employ gradient based sampling as well. Last but not least, *inplace_predict* can be preferred over *predict* when data is already on GPU. Both *QuantileDMatrix* and *inplace_predict* are automatically enabled if you are using the scikit-learn interface.

**CPU-GPU Interoperability**

The model can be used on any device regardless of the one used to train it. For instance, a model trained using GPU can still work on a CPU-only machine and vice versa. For more information about model serialization, see *Introduction to Model IO*.
Developer notes

The application may be profiled with annotations by specifying USE_NTVX to cmake. Regions covered by the 'Monitor' class in CUDA code will automatically appear in the n$ight profiler when verbosity is set to 3.

1.7 XGBoost Parameters

Before running XGBoost, we must set three types of parameters: general parameters, booster parameters and task parameters.

• General parameters relate to which booster we are using to do boosting, commonly tree or linear model
• Booster parameters depend on which booster you have chosen
• Learning task parameters decide on the learning scenario. For example, regression tasks may use different parameters with ranking tasks.
• Command line parameters relate to behavior of CLI version of XGBoost.
Parameters in R package

In R-package, you can use . (dot) to replace underscore in the parameters, for example, you can use max. depth to indicate max_depth. The underscore parameters are also valid in R.

- **Global Configuration**
- **General Parameters**
  - Parameters for Tree Booster
  - Parameters for Categorical Feature
  - Additional parameters for Dart Booster (booster=dart)
  - Parameters for Linear Booster (booster=gblinear)
- **Learning Task Parameters**
  - Parameters for Tweedie Regression (objective=reg:tweedie)
  - Parameter for using Pseudo-Huber (reg:pseudohubererror)
  - Parameter for using Quantile Loss (reg:quantileerror)
  - Parameter for using AFT Survival Loss (survival:aft) and Negative Log Likelihood of AFT metric (aft-nloglik)
  - Parameters for learning to rank (rank:ndcg, rank:map, rank:pairwise)
- **Command Line Parameters**

### 1.7.1 Global Configuration

The following parameters can be set in the global scope, using `xgboost.config_context()` (Python) or `xgb.set.config()` (R).

- **verbosity**: Verbosity of printing messages. Valid values of 0 (silent), 1 (warning), 2 (info), and 3 (debug).
- **use_rmm**: Whether to use RAPIDS Memory Manager (RMM) to allocate cache GPU memory. The primary memory is always allocated on the RMM pool when XGBoost is built (compiled) with the RMM plugin enabled. Valid values are `true` and `false`. See **Using XGBoost with RAPIDS Memory Manager (RMM) plugin** for details.

### 1.7.2 General Parameters

- **booster** [default= gbtree ]
  - Which booster to use. Can be gbtree, gblinear or dart; gbtree and dart use tree based models while gblinear uses linear functions.
- **device** [default= cpu ]

  Added in version 2.0.0.
  
  - Device for XGBoost to run. User can set it to one of the following values:
∗ cpu: Use CPU.
∗ cuda: Use a GPU (CUDA device).
∗ cuda:<ordinal>: <ordinal> is an integer that specifies the ordinal of the GPU (which GPU do you want to use if you have more than one devices).
∗ gpu: Default GPU device selection from the list of available and supported devices. Only cuda devices are supported currently.
∗ gpu:<ordinal>: Default GPU device selection from the list of available and supported devices. Only cuda devices are supported currently.

For more information about GPU acceleration, see XGBoost GPU Support. In distributed environments, ordinal selection is handled by distributed frameworks instead of XGBoost. As a result, using cuda:<ordinal> will result in an error. Use cuda instead.

• verbosity [default=1]
  – Verbosity of printing messages. Valid values are 0 (silent), 1 (warning), 2 (info), 3 (debug). Sometimes XGBoost tries to change configurations based on heuristics, which is displayed as warning message. If there’s unexpected behaviour, please try to increase value of verbosity.

• validate_parameters [default to false, except for Python, R and CLI interface]
  – When set to True, XGBoost will perform validation of input parameters to check whether a parameter is used or not. A warning is emitted when there’s unknown parameter.

• nthread [default to maximum number of threads available if not set]
  – Number of parallel threads used to run XGBoost. When choosing it, please keep thread contention and hyperthreading in mind.

• disable_default_eval_metric [default= false]
  – Flag to disable default eval metric. Set to 1 or true to disable.

Parameters for Tree Booster

• eta [default=0.3, alias: learning_rate]
  – Step size shrinkage used in update to prevent overfitting. After each boosting step, we can directly get the weights of new features, and eta shrinks the feature weights to make the boosting process more conservative.
  – range: [0,1]

• gamma [default=0, alias: min_split_loss]
  – Minimum loss reduction required to make a further partition on a leaf node of the tree. The larger gamma is, the more conservative the algorithm will be. Note that a tree where no splits were made might still contain a single terminal node with a non-zero score.
  – range: [0,∞]

• max_depth [default=6]
  – Maximum depth of a tree. Increasing this value will make the model more complex and more likely to overfit. 0 indicates no limit on depth. Beware that XGBoost aggressively consumes memory when training a deep tree. exact tree method requires non-zero value.
  – range: [0,∞]

• min_child_weight [default=1]
- Minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than \textit{min	extunderscore child	extunderscore weight}, then the building process will give up further partitioning. In linear regression task, this simply corresponds to minimum number of instances needed to be in each node. The larger \textit{min	extunderscore child	extunderscore weight} is, the more conservative the algorithm will be.
  - range: \([0, \infty]\)

- \textbf{max	extunderscore delta	extunderscore step} [default=0]
  - Maximum delta step we allow each leaf output to be. If the value is set to 0, it means there is no constraint. If it is set to a positive value, it can help making the update step more conservative. Usually this parameter is not needed, but it might help in logistic regression when class is extremely imbalanced. Set it to value of 1-10 might help control the update.
  - range: \([0, \infty]\)

- \textbf{subsample} [default=1]
  - Subsample ratio of the training instances. Setting it to 0.5 means that XGBoost would randomly sample half of the training data prior to growing trees. and this will prevent overfitting. Subsampling will occur once in every boosting iteration.
  - range: \((0,1]\)

- \textbf{sampling	extunderscore method} [default= uniform]
  - The method to use to sample the training instances.
    - \textit{uniform}: each training instance has an equal probability of being selected. Typically set \textit{subsample} \(\geq 0.5\) for good results.
    - \textit{gradient	extunderscore based}: the selection probability for each training instance is proportional to the regularized absolute value of gradients (more specifically, \(\sqrt{g^2 + \lambda h^2}\)). \textit{subsample} may be set to as low as 0.1 without loss of model accuracy. Note that this sampling method is only supported when \textit{tree	extunderscore method} is set to hist and the device is cuda; other tree methods only support \textit{uniform} sampling.

- \textbf{colsample	extunderscore bytree, colsample	extunderscore bylevel, colsample	extunderscore bynode} [default=1]
  - This is a family of parameters for subsampling of columns.
    - All \textit{colsample	extunderscore by*} parameters have a range of \((0, 1]\), the default value of 1, and specify the fraction of columns to be subsampled.
    - \textit{colsample	extunderscore bytree} is the subsample ratio of columns when constructing each tree. Subsampling occurs once for every tree constructed.
    - \textit{colsample	extunderscore bylevel} is the subsample ratio of columns for each level. Subsampling occurs once for every new depth level reached in a tree. Columns are subsampled from the set of columns chosen for the current tree.
    - \textit{colsample	extunderscore bynode} is the subsample ratio of columns for each node (split). Subsampling occurs once every time a new split is evaluated. Columns are subsampled from the set of columns chosen for the current level. This is not supported by the exact tree method.
    - \textit{colsample	extunderscore by*} parameters work cumulatively. For instance, the combination \{\textit{colsample	extunderscore bytree}:0.5, \textit{colsample	extunderscore bylevel}:0.5, \textit{colsample	extunderscore bynode}:0.5\} with 64 features will leave 8 features to choose from at each split.

  Using the Python or the R package, one can set the \textit{feature	extunderscore weights} for \texttt{DMatrix} to define the probability of each feature being selected when using column sampling. There’s a similar parameter for \textit{fit} method in sklearn interface.

- \textbf{lambda} [default=1, alias: reg	extunderscore lambda]
– L2 regularization term on weights. Increasing this value will make model more conservative.
– range: \([0, \infty]\)

• **alpha** [default=0, alias: `reg_alpha`]
  – L1 regularization term on weights. Increasing this value will make model more conservative.
  – range: \([0, \infty]\)

• **tree_method** string [default= `auto`]
  – The tree construction algorithm used in XGBoost. See description in the reference paper and *Tree Methods*.
  – Choices: `auto`, `exact`, `approx`, `hist`, this is a combination of commonly used updaters. For other updaters like `refresh`, set the parameter `updater` directly.
    * `auto`: Same as the `hist` tree method.
    * `exact`: Exact greedy algorithm. Enumerates all split candidates.
    * `approx`: Approximate greedy algorithm using quantile sketch and gradient histogram.
    * `hist`: Faster histogram optimized approximate greedy algorithm.

• **scale_pos_weight** [default=1]
  – Control the balance of positive and negative weights, useful for unbalanced classes. A typical value to consider: \(\text{sum(negative instances)} / \text{sum(positive instances)}\). See Parameters Tuning for more discussion. Also, see Higgs Kaggle competition demo for examples: R, py1, py2, py3.

• **updater**
  – A comma separated string defining the sequence of tree updaters to run, providing a modular way to construct and to modify the trees. This is an advanced parameter that is usually set automatically, depending on some other parameters. However, it could be also set explicitly by a user. The following updaters exist:
    * `grow_colmaker`: non-distributed column-based construction of trees.
    * `grow_histmaker`: distributed tree construction with row-based data splitting based on global proposal of histogram counting.
    * `grow_quantile_histmaker`: Grow tree using quantized histogram.
    * `grow_gpu_hist`: Enabled when `tree_method` is set to `hist` along with `device=cuda`.
    * `grow_gpu_approx`: Enabled when `tree_method` is set to `approx` along with `device=cuda`.
    * `sync`: synchronizes trees in all distributed nodes.
    * `refresh`: refreshes tree’s statistics and/or leaf values based on the current data. Note that no random subsampling of data rows is performed.
    * `prune`: prunes the splits where loss < `min_split_loss` (or gamma) and nodes that have depth greater than `max_depth`.

• **refresh_leaf** [default=1]
  – This is a parameter of the `refresh` updater. When this flag is 1, tree leafs as well as tree nodes’ stats are updated. When it is 0, only node stats are updated.

• **process_type** [default= `default`]
  – A type of boosting process to run.
  – Choices: `default`, `update`
    * `default`: The normal boosting process which creates new trees.
**update**: Starts from an existing model and only updates its trees. In each boosting iteration, a tree from the initial model is taken, a specified sequence of updaters is run for that tree, and a modified tree is added to the new model. The new model would have either the same or smaller number of trees, depending on the number of boosting iterations performed. Currently, the following built-in updaters could be meaningfully used with this process type: refresh, prune. With process_type=update, one cannot use updaters that create new trees.

- **grow_policy** [default= depthwise]
  - Controls a way new nodes are added to the tree.
  - Currently supported only if tree_method is set to hist or approx.
  - Choices: depthwise, lossguide
    - * depthwise: split at nodes closest to the root.
    - * lossguide: split at nodes with highest loss change.
- **max_leaves** [default=0]
  - Maximum number of nodes to be added. Not used by exact tree method.
- **max_bin**, [default=256]
  - Only used if tree_method is set to hist or approx.
  - Maximum number of discrete bins to bucket continuous features.
  - Increasing this number improves the optimality of splits at the cost of higher computation time.
- **num_parallel_tree**, [default=1]
  - Number of parallel trees constructed during each iteration. This option is used to support boosted random forest.
- **monotone_constraints**
  - Constraint of variable monotonicity. See Monotonic Constraints for more information.
- **interaction_constraints**
  - Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nest list, e.g. `[[0, 1], [2, 3, 4]]`, where each inner list is a group of indices of features that are allowed to interact with each other. See Feature Interaction Constraints for more information.
- **multi_strategy**, [default = one_output_per_tree]
  - The strategy used for training multi-target models, including multi-target regression and multi-class classification. See Multiple Outputs for more information.
    - * one_output_per_tree: One model for each target.
- **max_cached_hist_node**, [default = 65536]
  - Maximum number of cached nodes for CPU histogram.
  - Added in version 2.0.0.
– For most of the cases this parameter should not be set except for growing deep trees on CPU.

Parameters for Categorical Feature

These parameters are only used for training with categorical data. See Categorical Data for more information.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>These parameters are experimental. <strong>exact</strong> tree method is not yet supported.</td>
</tr>
</tbody>
</table>

- **max_cat_to_onehot**
  - Added in version 1.6.0.
  - A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes.

- **max_cat_threshold**
  - Added in version 1.7.0.
  - Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting.

Additional parameters for Dart Booster (booster=dart)

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Using <code>predict()</code> with DART booster</td>
</tr>
</tbody>
</table>

If the booster object is DART type, `predict()` will perform dropouts, i.e. only some of the trees will be evaluated. This will produce incorrect results if data is not the training data. To obtain correct results on test sets, set `iteration_range` to a nonzero value, e.g.

```python
preds = bst.predict(dtest, iteration_range=(0, num_round))
```

- **sample_type** [default= uniform]
  - Type of sampling algorithm.
    - **uniform**: dropped trees are selected uniformly.
    - **weighted**: dropped trees are selected in proportion to weight.

- **normalize_type** [default= tree]
  - Type of normalization algorithm.
    - **tree**: new trees have the same weight of each of dropped trees.
      - Weight of new trees are \( \frac{1}{k + \text{learning}_\text{rate}} \).
      - Dropped trees are scaled by a factor of \( \frac{k}{k + \text{learning}_\text{rate}} \).
    - **forest**: new trees have the same weight of sum of dropped trees (forest).
      - Weight of new trees are \( \frac{1}{1 + \text{learning}_\text{rate}} \).
· Dropped trees are scaled by a factor of $\frac{1}{1 + \text{learning_rate}}$.

- rate_drop [default=0.0]
  - Dropout rate (a fraction of previous trees to drop during the dropout).
  - range: [0.0, 1.0]

- one_drop [default=0]
  - When this flag is enabled, at least one tree is always dropped during the dropout (allows Binomial-plus-one or epsilon-dropout from the original DART paper).

- skip_drop [default=0.0]
  - Probability of skipping the dropout procedure during a boosting iteration.
    * If a dropout is skipped, new trees are added in the same manner as gbtree.
    * Note that non-zero skip_drop has higher priority than rate_drop or one_drop.
  - range: [0.0, 1.0]

Parameters for Linear Booster (booster=gblinear)

- lambda [default=0, alias: reg_lambda]
  - L2 regularization term on weights. Increasing this value will make model more conservative. Normalised to number of training examples.

- alpha [default=0, alias: reg_alpha]
  - L1 regularization term on weights. Increasing this value will make model more conservative. Normalised to number of training examples.

- updater [default=shotgun]
  - Choice of algorithm to fit linear model
    * shotgun: Parallel coordinate descent algorithm based on shotgun algorithm. Uses ‘hogwild’ parallelism and therefore produces a nondeterministic solution on each run.
    * coord_descent: Ordinary coordinate descent algorithm. Also multithreaded but still produces a deterministic solution. When the device parameter is set to cuda or gpu, a GPU variant would be used.

- feature_selector [default=cyclic]
  - Feature selection and ordering method
    * cyclic: Deterministic selection by cycling through features one at a time.
    * shuffle: Similar to cyclic but with random feature shuffling prior to each update.
    * random: A random (with replacement) coordinate selector.
    * greedy: Select coordinate with the greatest gradient magnitude. It has $O(\text{num\_feature}^2)$ complexity. It is fully deterministic. It allows restricting the selection to top_k features per group with the largest magnitude of univariate weight change, by setting the top_k parameter. Doing so would reduce the complexity to $O(\text{num\_feature}\times\text{top\_k})$.
    * thrifty: Thrifty, approximately-greedy feature selector. Prior to cyclic updates, reorders features in descending magnitude of their univariate weight changes. This operation is multithreaded and is a linear complexity approximation of the quadratic greedy selection. It allows restricting the selection to
top_k features per group with the largest magnitude of univariate weight change, by setting the top_k parameter.

- top_k [default=0]
  - The number of top features to select in greedy and thrifty feature selector. The value of 0 means using all the features.

### 1.7.3 Learning Task Parameters

Specify the learning task and the corresponding learning objective. The objective options are below:

- objective [default=reg:squarederror]
  - reg:squarederror: regression with squared loss.
  - reg:squaredlogerror: regression with squared log loss $\frac{1}{2} \left[ \log(pred + 1) - \log(label + 1) \right]^2$. All input labels are required to be greater than -1. Also, see metric rmsle for possible issue with this objective.
  - reg:logistic: logistic regression, output probability
  - reg:pseudohubererror: regression with Pseudo Huber loss, a twice differentiable alternative to absolute loss.
  - reg:absoluteerror: Regression with L1 error. When tree model is used, leaf value is refreshed after tree construction. If used in distributed training, the leaf value is calculated as the mean value from all workers, which is not guaranteed to be optimal.
    Added in version 1.7.0.
  - reg:quantileerror: Quantile loss, also known as pinball loss. See later sections for its parameter and Quantile Regression for a worked example.
    Added in version 2.0.0.
  - binary:logistic: logistic regression for binary classification, output probability
  - binary:logitraw: logistic regression for binary classification, output score before logistic transformation
  - binary:hinge: hinge loss for binary classification. This makes predictions of 0 or 1, rather than producing probabilities.
  - count:poisson: Poisson regression for count data, output mean of Poisson distribution.
    * max_delta_step is set to 0.7 by default in Poisson regression (used to safeguard optimization)
  - survival:cox: Cox regression for right censored survival time data (negative values are considered right censored). Note that predictions are returned on the hazard ratio scale (i.e., as $HR = \exp(marginal\_prediction)$ in the proportional hazard function $h(t) = h0(t) * HR$).
  - survival:aft: Accelerated failure time model for censored survival time data. See Survival Analysis with Accelerated Failure Time for details.
  - multi:softmax: set XGBoost to do multiclass classification using the softmax objective, you also need to set num_class(number of classes)
  - multi:softprob: same as softmax, but output a vector of $ndata \times nclass$, which can be further reshaped to $ndata \times nclass$ matrix. The result contains predicted probability of each data point belonging to each class.
  - rank:ndcg: Use LambdaMART to perform pair-wise ranking where Normalized Discounted Cumulative Gain (NDCG) is maximized. This objective supports position debiasing for click data.
- **rank:map**: Use LambdaMART to perform pair-wise ranking where Mean Average Precision (MAP) is maximized.

- **rank:pairwise**: Use LambdaRank to perform pair-wise ranking using the ranknet objective.

- **reg:gamma**: gamma regression with log-link. Output is a mean of gamma distribution. It might be useful, e.g., for modeling insurance claims severity, or for any outcome that might be gamma-distributed.

- **reg:tweedie**: Tweedie regression with log-link. It might be useful, e.g., for modeling total loss in insurance, or for any outcome that might be Tweedie-distributed.

- **base_score**
  - The initial prediction score of all instances, global bias
  - The parameter is automatically estimated for selected objectives before training. To disable the estimation, specify a real number argument.
  - If base_margin is supplied, base_score will not be added.
  - For sufficient number of iterations, changing this value will not have too much effect.

  See *Intercept* for more info.

- **eval_metric** [default according to objective]
  - Evaluation metrics for validation data, a default metric will be assigned according to objective (rmse for regression, and logloss for classification, mean average precision for rank:map, etc.)
  - User can add multiple evaluation metrics. Python users: remember to pass the metrics in as list of parameters pairs instead of map, so that latter eval_metric won’t override previous ones
  - The choices are listed below:
    * **rmse**: root mean square error
    * **rmsle**: root mean square log error: \( \sqrt{\frac{1}{N} \left[ \log(pred + 1) - \log(label + 1) \right]^2} \). Default metric of reg:squaredlogerror objective. This metric reduces errors generated by outliers in dataset. But because log function is employed, rmsle might output nan when prediction value is less than -1. See reg:squaredlogerror for other requirements.
    * **mae**: mean absolute error
    * **mape**: mean absolute percentage error
    * **mphe**: mean Pseudo Huber error. Default metric of reg:pseudohubererror objective.
    * **logloss**: negative log-likelihood
    * **error**: Binary classification error rate. It is calculated as \( \#(\text{wrong cases})/\#(\text{all cases}) \). For the predictions, the evaluation will regard the instances with prediction value larger than 0.5 as positive instances, and the others as negative instances.
    * **error@t**: a different than 0.5 binary classification threshold value could be specified by providing a numerical value through ‘t’.
    * **merror**: Multiclass classification error rate. It is calculated as \( \#(\text{wrong cases})/\#(\text{all cases}) \).
    * **mlogloss**: Multiclass logloss.
      - When used with binary classification, the objective should be binary:logistic or similar functions that work on probability.
When used with multi-class classification, objective should be `multi:softprob` instead of `multi:softmax`, as the latter doesn’t output probability. Also the AUC is calculated by 1-vs-rest with reference class weighted by class prevalence.

When used with LTR task, the AUC is computed by comparing pairs of documents to count correctly sorted pairs. This corresponds to pairwise learning to rank. The implementation has some issues with average AUC around groups and distributed workers not being well-defined.

On a single machine the AUC calculation is exact. In a distributed environment the AUC is a weighted average over the AUC of training rows on each node - therefore, distributed AUC is an approximation sensitive to the distribution of data across workers. Use another metric in distributed environments if precision and reproducibility are important.

When input dataset contains only negative or positive samples, the output is `NaN`. The behavior is implementation defined, for instance, scikit-learn returns 0.5 instead.

- **aucpr**: Area under the PR curve. Available for classification and learning-to-rank tasks. After XGBoost 1.6, both of the requirements and restrictions for using aucpr in classification problem are similar to auc. For ranking task, only binary relevance label $y \in [0, 1]$ is supported. Different from map (mean average precision), aucpr calculates the interpolated area under precision recall curve using continuous interpolation.

- **pre**: Precision at $k$. Supports only learning to rank task.

- **ndcg**: Normalized Discounted Cumulative Gain

- **map**: Mean Average Precision

  The average precision is defined as:

  $AP@l = \frac{1}{\min(l, N)} \sum_{k=1}^{l} P@k \cdot I(k)$

  where $I(k)$ is an indicator function that equals to 1 when the document at $k$ is relevant and 0 otherwise. The $P@k$ is the precision at $k$, and $N$ is the total number of relevant documents. Lastly, the mean average precision is defined as the weighted average across all queries.

- **ndcg@n, map@n, pre@n**: $n$ can be assigned as an integer to cut off the top positions in the lists for evaluation.

- **ndcg-, map-, ndcg@n-, map@n-**: In XGBoost, the NDCG and MAP evaluate the score of a list without any positive samples as 1. By appending "-" to the evaluation metric name, we can ask XGBoost to evaluate these scores as 0 to be consistent under some conditions.

- **poisson-nloglik**: negative log-likelihood for Poisson regression

- **gamma-nloglik**: negative log-likelihood for gamma regression

- **cox-nloglik**: negative partial log-likelihood for Cox proportional hazards regression

- **gamma-deviance**: residual deviance for gamma regression

- **tweedie-nloglik**: negative log-likelihood for Tweedie regression (at a specified value of the `tweedie_variance_power` parameter)

- **aft-nloglik**: Negative log likelihood of Accelerated Failure Time model. See Survival Analysis with Accelerated Failure Time for details.

- **interval-regression-accuracy**: Fraction of data points whose predicted labels fall in the interval-censored labels. Only applicable for interval-censored data. See Survival Analysis with Accelerated Failure Time for details.
• seed [default=0]
  – Random number seed. In the R package, if not specified, instead of defaulting to seed ‘zero’, will take a random seed through R’s own RNG engine.

• seed_per_iteration [default= false]
  – Seed PRNG deterministicly via iterator number.

**Parameters for Tweedie Regression (objective=reg:tweedie)**

• tweedie_variance_power [default=1.5]
  – Parameter that controls the variance of the Tweedie distribution \( \text{var}(y) \sim \text{E}(y)^{\text{tweedie_variance_power}} \)
  – range: (1,2)
  – Set closer to 2 to shift towards a gamma distribution
  – Set closer to 1 to shift towards a Poisson distribution.

**Parameter for using Pseudo-Huber (reg:pseudohubererror)**

• huber_slope : A parameter used for Pseudo-Huber loss to define the \( \delta \) term. [default = 1.0]

**Parameter for using Quantile Loss (reg:quantileerror)**

• quantile_alpha: A scalar or a list of targeted quantiles.
  Added in version 2.0.0.

**Parameter for using AFT Survival Loss (survival:aft) and Negative Log Likelihood of AFT metric (aft-nloglik)**

• aft_loss_distribution: Probability Density Function, normal, logistic, or extreme.

**Parameters for learning to rank (rank:ndcg, rank:map, rank:pairwise)**

These are parameters specific to learning to rank task. See *Learning to Rank* for an in-depth explanation.

• lambdarank_pair_method [default = topk]
  How to construct pairs for pair-wise learning.
  – mean: Sample lambdarank_num_pair_per_sample pairs for each document in the query list.
  – topk: Focus on top-lambdarank_num_pair_per_sample documents. Construct \( |\text{query}| \) pairs for each document at the top-lambdarank_num_pair_per_sample ranked by the model.

• lambdarank_num_pair_per_sample [range = [1, \( \infty \)])
  It specifies the number of pairs sampled for each document when pair method is mean, or the truncation level for queries when the pair method is topk. For example, to train with ndcg@6, set lambdarank_num_pair_per_sample to 6 and lambdarank_pair_method to topk.
• `lambdarank_normalization` [default = true]
  
  Added in version 2.1.0.
  
  Whether to normalize the leaf value by lambda gradient. This can sometimes stagnate the training progress.

• `lambdarank_unbiased` [default = false]

  Specify whether do we need to debias input click data.

• `lambdarank_bias_norm` [default = 2.0]

  $L_p$ normalization for position debiasing, default is $L_2$. Only relevant when `lambdarank_unbiased` is set to true.

• `ndcg_exp_gain` [default = true]

  Whether we should use exponential gain function for NDCG. There are two forms of gain function for NDCG, one is using relevance value directly while the other is using $2^{rel} - 1$ to emphasize on retrieving relevant documents. When `ndcg_exp_gain` is true (the default), relevance degree cannot be greater than 31.

### 1.7.4 Command Line Parameters

The following parameters are only used in the console version of XGBoost

• `num_round`  
  
  The number of rounds for boosting

• `data`  
  
  The path of training data

• `test:data`  
  
  The path of test data to do prediction

• `save_period` [default=0]  
  
  The period to save the model. Setting `save_period=10` means that for every 10 rounds XGBoost will save the model. Setting it to 0 means not saving any model during the training.

• `task` [default= train] options: train, pred, eval, dump  
  
  – train: training using data  
  
  – pred: making prediction for `test:data`  
  
  – eval: for evaluating statistics specified by `eval[name]=filename`  
  
  – dump: for dump the learned model into text format

• `model_in` [default=NULL]  
  
  – Path to input model, needed for `test`, `eval`, `dump` tasks. If it is specified in training, XGBoost will continue training from the input model.

• `model_out` [default=NULL]  
  
  – Path to output model after training finishes. If not specified, XGBoost will output files with such names as `0003.model` where `0003` is number of boosting rounds.

• `model_dir` [default= models/]  
  
  – The output directory of the saved models during training

• `fmap`
1.8 Prediction

There are a number of prediction functions in XGBoost with various parameters. This document attempts to clarify some of confusions around prediction with a focus on the Python binding. R package is similar when strict_shape is specified (see below).

1.8.1 Prediction Options

There are a number of different prediction options for the `xgboost.Booster.predict()` method, ranging from pred_contribs to pred_leaf. The output shape depends on types of prediction. Also for multi-class classification problem, XGBoost builds one tree for each class and the trees for each class are called a “group” of trees, so output dimension may change due to used model. After 1.4 release, we added a new parameter called strict_shape, one can set it to True to indicate a more restricted output is desired. Assuming you are using `xgboost.Booster`, here is a list of possible returns:

- When using normal prediction with strict_shape set to True:
  
  Output is a 2-dim array with first dimension as rows and second as groups. For regression/survival/ranking/binary classification this is equivalent to a column vector with shape[1] == 1. But for multi-class with multi:softprob the number of columns equals to number of classes. If strict_shape is set to False then XGBoost might output 1 or 2 dim array.

- When using output_margin to avoid transformation and strict_shape is set to True:

  Similar to the previous case, output is a 2-dim array, except for that multi:softmax has equivalent output shape of multi:softprob due to dropped transformation. If strict shape is set to False then output can have 1 or 2 dim depending on used model.

- When using pred_contribs with strict_shape set to True:

  Output is a 3-dim array, with (rows, groups, columns + 1) as shape. Whether approx_contribs is used does not change the output shape. If the strict shape parameter is not set, it can be a 2 or 3 dimension array depending on whether multi-class model is being used.

- When using pred_interactions with strict_shape set to True:

  Output is a 4-dim array, with (rows, groups, columns + 1, columns + 1) as shape. Like the predict contribution case, whether approx_contribs is used does not change the output shape. If strict shape is set to False, it can have 3 or 4 dims depending on the underlying model.
• When using *pred_leaf* with *strict_shape* set to True:

Output is a 4-dim array with *(n_samples, n_iterations, n_classes, n_trees_in_forest)* as shape. *n_trees_in_forest* is specified by the *numb_parallel_tree* during training. When strict shape is set to False, output is a 2-dim array with last 3 dims concatenated into 1. Also the last dimension is dropped if it equals to 1. When using *apply* method in scikit learn interface, this is set to False by default.

For R package, when *strict_shape* is specified, an array is returned, with the same value as Python except R array is column-major while Python numpy array is row-major, so all the dimensions are reversed. For example, for a Python *predict_leaf* output obtained by having *strict_shape=True* has 4 dimensions: *(n_samples, n_iterations, n_classes, n_trees_in_forest)*, while R with *strict_shape=TRUE* outputs *(n_trees_in_forest, n_classes, n_iterations, n_samples)*.

Other than these prediction types, there’s also a parameter called *iteration_range*, which is similar to model slicing. But instead of actually splitting up the model into multiple stacks, it simply returns the prediction formed by the trees within range. Number of trees created in each iteration equals to \( \text{trees}_i = \text{num_class} \times \text{num_parallel_tree} \). So if you are training a boosted random forest with size of 4, on the 3-class classification dataset, and want to use the first 2 iterations of trees for prediction, you need to provide *iteration_range*=(0, 2). Then the first \( 2 \times 3 \times 4 \) trees will be used in this prediction.

### 1.8.2 Early Stopping

When a model is trained with early stopping, there is an inconsistent behavior between native Python interface and sklearn/R interfaces. By default on R and sklearn interfaces, the *best_iteration* is automatically used so prediction comes from the best model. But with the native Python interface `xgboost.Booster.predict()` and `xgboost.Booster.inplace_predict()` uses the full model. Users can use *best_iteration* attribute with *iteration_range* parameter to achieve the same behavior. Also the *save_best* parameter from `xgboost.callback.EarlyStopping` might be useful.

### 1.8.3 Base Margin

There’s a training parameter in XGBoost called *base_score*, and a meta data for `DMatrix` called *base_margin* (which can be set in `fit` method if you are using scikit-learn interface). They specify the global bias for boosted model. If the latter is supplied then former is ignored. *base_margin* can be used to train XGBoost model based on other models. See demos on boosting from predictions.

### 1.8.4 Staged Prediction

Using the native interface with `DMatrix`, prediction can be staged (or cached). For example, one can first predict on the first 4 trees then run prediction on 8 trees. After running the first prediction, result from first 4 trees are cached so when you run the prediction with 8 trees XGBoost can reuse the result from previous prediction. The cache expires automatically upon next prediction, train or evaluation if the cached `DMatrix` object is expired (like going out of scope and being collected by garbage collector in your language environment).
1.8.5 In-place Prediction

Traditionally XGBoost accepts only DMatrix for prediction, with wrappers like scikit-learn interface the construction happens internally. We added support for in-place predict to bypass the construction of DMatrix, which is slow and memory consuming. The new predict function has limited features but is often sufficient for simple inference tasks. It accepts some commonly found data types in Python like numpy.ndarray, scipy.sparse.csr_matrix and cudf.DataFrame instead of xgboost.DMatrix. You can call xgboost.Booster.inplace_predict() to use it. Be aware that the output of in-place prediction depends on input data type, when input is on GPU data output is cupy.ndarray, otherwise a numpy.ndarray is returned.

1.8.6 Thread Safety

After 1.4 release, all prediction functions including normal predict with various parameters like shap value computation and inplace_predict are thread safe when underlying booster is gbtree or dart, which means as long as tree model is used, prediction itself should thread safe. But the safety is only guaranteed with prediction. If one tries to train a model in one thread and provide prediction at the other using the same model the behaviour is undefined. This happens easier than one might expect, for instance we might accidentally call clf.set_params() inside a predict function:

```python
def predict_fn(clf: xgb.XGBClassifier, X):
    X = preprocess(X)
    clf.set_params(n_jobs=1)  # NOT safe!
    return clf.predict_proba(X, iteration_range=(0, 10))

with ThreadPoolExecutor(max_workers=10) as e:
    e.submit(predict_fn, ...)  # NOT safe!
```

1.8.7 Privacy-Preserving Prediction

Concrete ML is a third-party open-source library developed by Zama that proposes gradient boosting classes similar to ours, but predicting directly over encrypted data, thanks to Fully Homomorphic Encryption. A simple example would be as follows:

```python
from sklearn.datasets import make_classification
from sklearn.model_selection import train_test_split
from concrete.ml.sklearn import XGBClassifier

x, y = make_classification(n_samples=100, class_sep=2, n_features=30, random_state=42)
X_train, X_test, y_train, y_test = train_test_split(
    x, y, test_size=10, random_state=42
)

# Train in the clear and quantize the weights
model = XGBClassifier()
model.fit(X_train, y_train)

# Simulate the predictions in the clear
y_pred_clear = model.predict(X_test)

# Compile in FHE
model.compile(X_train)
```

(continues on next page)
# Generate keys
model.fhe_circuit.keygen()

# Run the inference on encrypted inputs!
y_pred_fhe = model.predict(X_test, fhe="execute")

print("In clear :", y_pred_clear)
print("In FHE :", y_pred_fhe)
print(f"Similarity: {int((y_pred_fhe == y_pred_clear).mean() * 100)}%")

More information and examples are given in the Concrete ML documentation.

1.9 Tree Methods

For training boosted tree models, there are 2 parameters used for choosing algorithms, namely updater and tree_method. XGBoost has 3 built-in tree methods, namely exact, approx and hist. Along with these tree methods, there are also some free standing updaters including refresh, prune and sync. The parameter updater is more primitive than tree_method as the latter is just a pre-configuration of the former. The difference is mostly due to historical reasons that each updater requires some specific configurations and might have missing features. As we are moving forward, the gap between them is becoming more and more irrelevant. We will collectively document them under tree methods.

1.9.1 Exact Solution

Exact means XGBoost considers all candidates from data for tree splitting, but underlying the objective is still interpreted as a Taylor expansion.

1. exact: The vanilla gradient boosting tree algorithm described in reference paper. During split-finding, it iterates over all entries of input data. It’s more accurate (among other greedy methods) but computationally slower in compared to other tree methods. Further more, its feature set is limited. Features like distributed training and external memory that require approximated quantiles are not supported. This tree method can be used with the parameter tree_method set to exact.

1.9.2 Approximated Solutions

As exact tree method is slow in computation performance and difficult to scale, we often employ approximated training algorithms. These algorithms build a gradient histogram for each node and iterate through the histogram instead of real dataset. Here we introduce the implementations in XGBoost.

1. approx tree method: An approximation tree method described in reference paper. It runs sketching before building each tree using all the rows (rows belonging to the root). Hessian is used as weights during sketch. The algorithm can be accessed by setting tree_method to approx.

2. hist tree method: An approximation tree method used in LightGBM with slight differences in implementation. It runs sketching before training using only user provided weights instead of hessian. The subsequent per-node histogram is built upon this global sketch. This is the fastest algorithm as it runs sketching only once. The algorithm can be accessed by setting tree_method to hist.
1.9.3 Implications

Some objectives like `reg:squarederror` have constant hessian. In this case, the `hist` should be preferred as weighted sketching doesn’t make sense with constant weights. When using non-constant hessian objectives, sometimes `approx` yields better accuracy, but with slower computation performance. Most of the time using `hist` with higher `max_bin` can achieve similar or even superior accuracy while maintaining good performance. However, as `xgboost` is largely driven by community effort, the actual implementations have some differences than pure math description. Result might be slightly different than expectation, which we are currently trying to overcome.

1.9.4 Other Updaters

1. Prune: It prunes the existing trees. `prune` is usually used as part of other tree methods. To use pruner independently, one needs to set the process type to update by: `{"process_type": "update", "updater": "prune"}`. With this set of parameters, during training, XGBoost will prune the existing trees according to 2 parameters `min_split_loss` (gamma) and `max_depth`.

2. Refresh: Refresh the statistic of built trees on a new training dataset. Like the pruner, To use refresh independently, one needs to set the process type to update: `{"process_type": "update", "updater": "refresh"}`. During training, the updater will change statistics like `cover` and `weight` according to the new training dataset. When `refresh_leaf` is also set to true (default), XGBoost will update the leaf value according to the new leaf weight, but the tree structure (split condition) itself doesn’t change.

There are examples on both training continuation (adding new trees) and using update process on `demo/guide-python`. Also checkout the `process_type` parameter in `XGBoost Parameters`.

3. Sync: Synchronize the tree among workers when running distributed training.

1.9.5 Removed Updaters

3 Updaters were removed during development due to maintainability. We describe them here solely for the interest of documentation.

1. Distributed colmaker, which was a distributed version of exact tree method. It required specialization for column based splitting strategy and a different prediction procedure. As the exact tree method is slow by itself and scaling is even less efficient, we removed it entirely.

2. skmaker: Per-node weighted sketching employed by `grow_local_histmaker` is slow, the `skmaker` was unmaintained and seems to be a workaround trying to eliminate the histogram creation step and uses sketching values directly during split evaluation. It was never tested and contained some unknown bugs, we decided to remove it and focus our resources on more promising algorithms instead. For accuracy, most of the time `approx` and `hist` are enough with some parameters tuning, so removing them don’t have any real practical impact.

3. `grow_local_histmaker` updater: An approximation tree method described in reference paper. This updater was rarely used in practice so it was still an updater rather than tree method. During split finding, it first runs a weighted GK sketching for data points belong to current node to find split candidates, using hessian as weights. The histogram is built upon this per-node sketch. It was faster than `exact` in some applications, but still slow in computation. It was removed because it depended on Rabit’s customized reduction function that handles all the data structure that can be serialized/deserialized into fixed size buffer, which is not directly supported by NCCL or federated learning gRPC, making it hard to refactor into a common allreducer interface.
### 1.9.6 Feature Matrix

Following table summarizes some differences in supported features between 4 tree methods, \( T \) means supported while \( F \) means unsupported.

<table>
<thead>
<tr>
<th></th>
<th>Exact</th>
<th>Approx</th>
<th>Approx (GPU)</th>
<th>Hist</th>
<th>Hist (GPU)</th>
</tr>
</thead>
<tbody>
<tr>
<td>grow_policy</td>
<td>Depth-wise</td>
<td>depthwise/lossguide</td>
<td>depthwise/lossguide</td>
<td>depthwise/lossguide</td>
<td>depthwise/lossguide</td>
</tr>
<tr>
<td>max_leaves sampling</td>
<td>uniformly</td>
<td>uniform</td>
<td>T gradient_based/uniform</td>
<td>T uniform</td>
<td>T gradient_based/uniform</td>
</tr>
<tr>
<td>sampling method</td>

<td>T</td>
<td>P</td>
<td>T</td>
<td>P</td>
</tr>
<tr>
<td>Distributed</td>
<td>F</td>
<td>T</td>
<td>T</td>
<td>T</td>
<td>T</td>
</tr>
</tbody>
</table>

Features/parameters that are not mentioned here are universally supported for all 3 tree methods (for instance, column sampling and constraints). The \( P \) in external memory means special handling. Please note that both categorical data and external memory are experimental.

### 1.10 XGBoost Python Package

This page contains links to all the python related documents on python package. To install the package, checkout Installation Guide.

#### 1.10.1 Contents

**Python Package Introduction**

This document gives a basic walkthrough of the xgboost package for Python. The Python package is consisted of 3 different interfaces, including native interface, scikit-learn interface and dask interface. For introduction to dask interface please see Distributed XGBoost with Dask.

**List of other Helpful Links**

- XGBoost Python Feature Walkthrough
- Python API Reference

**Contents**

- Install XGBoost
- Data Interface
  - Supported data structures for various XGBoost functions
    - * Markers
    - * Table Header
* Support Matrix

- Setting Parameters
- Training
- Early Stopping
- Prediction
- Plotting
- Scikit-Learn interface

Install XGBoost

To install XGBoost, follow instructions in Installation Guide.

To verify your installation, run the following in Python:

```python
import xgboost as xgb
```

Data Interface

The XGBoost Python module is able to load data from many different types of data format including both CPU and GPU data structures. For a complete list of supported data types, please reference the Supported data structures for various XGBoost functions. For a detailed description of text input formats, please visit Text Input Format of DMatrix.

The input data is stored in a DMatrix object. For the sklearn estimator interface, a DMatrix or a QuantileDMatrix is created depending on the chosen algorithm and the input, see the sklearn API reference for details. We will illustrate some of the basic input types with the DMatrix here.

- To load a NumPy array into DMatrix:
  ```python
data = np.random.rand(5, 10)  # 5 entities, each contains 10 features
label = np.random.randint(2, size=5)  # binary target
dtrain = xgb.DMatrix(data, label=label)
```

- To load a scipy.sparse array into DMatrix:
  ```python
csr = scipy.sparse.csr_matrix((dat, (row, col)))
dtrain = xgb.DMatrix(csr)
```

- To load a Pandas data frame into DMatrix:
  ```python
data = pandas.DataFrame(np.arange(12).reshape((4,3)), columns=['a', 'b', 'c'])
label = pandas.DataFrame(np.random.randint(2, size=4))
dtrain = xgb.DMatrix(data, label=label)
```

- Saving DMatrix into a XGBoost binary file will make loading faster:
  ```python
dtrain = xgb.DMatrix('train.svm.txt?format=libsvm')
dtrain.save_binary('train.buffer')
```

- Missing values can be replaced by a default value in the DMatrix constructor:
Weights can be set when needed:

```python
w = np.random.rand(5, 1)
dtrain = xgb.DMatrix(data, label=label, missing=np.NaN, weight=w)
```

When performing ranking tasks, the number of weights should be equal to number of groups.

To load a LIBSVM text file or a XGBoost binary file into `DMatrix`:

```python
dtrain = xgb.DMatrix('train.svm.txt?format=libsvm')
dtest = xgb.DMatrix('test.svm.buffer')
```

The parser in XGBoost has limited functionality. When using Python interface, it’s recommended to use sklearn `load_svmlight_file` or other similar utilities than XGBoost’s built-in parser.

To load a CSV file into `DMatrix`:

```python
# label_column specifies the index of the column containing the true label
dtrain = xgb.DMatrix('train.csv?format=csv&label_column=0')
dtest = xgb.DMatrix('test.csv?format=csv&label_column=0')
```

The parser in XGBoost has limited functionality. When using Python interface, it’s recommended to use pandas `read_csv` or other similar utilities than XGBoost’s built-in parser.

**Supported data structures for various XGBoost functions**

**Markers**

- T: Supported.
- F: Not supported.
- NE: Invalid type for the use case. For instance, `pd.Series` can not be multi-target label.
- NPA: Support with the help of numpy array.
- CPA: Support with the help of cupy array.
- SciCSR: Support with the help of scripy sparse CSR. The conversion to scipy CSR may or may not be possible. Raise a type error if conversion fails.
- FF: We can look forward to having its support in recent future if requested.
- empty: To be filled in.
Table Header

- X means predictor matrix.
- Meta info: label, weight, etc.
- Multi Label: 2-dim label for multi-target.
- Others: Anything else that we don’t list here explicitly including formats like lil, dia, bsr. XGBoost will try to convert it into scipy csr.

Setting Parameters

XGBoost can use either a list of pairs or a dictionary to set parameters. For instance:

- Booster parameters

```python
param = {'max_depth': 2, 'eta': 1, 'objective': 'binary:logistic'}
param['nthread'] = 4
param['eval_metric'] = 'auc'
```

- You can also specify multiple eval metrics:
Training

Training a model requires a parameter list and data set.

```python
num_round = 10
bst = xgb.train(param, dtrain, num_round, evallist)
```

After training, the model can be saved.

```python
bst.save_model('0001.model')
```

The model and its feature map can also be dumped to a text file.

```python
# dump model
bst.dump_model('dump.raw.txt')
# dump model with feature map
bst.dump_model('dump.raw.txt', 'featmap.txt')
```

A saved model can be loaded as follows:

```python
bst = xgb.Booster({'nthread': 4})  # init model
bst.load_model('model.bin')  # load model data
```

Methods including `update` and `boost` from `xgb.Booster` are designed for internal usage only. The wrapper function `xgboost.train` does some pre-configuration including setting up caches and some other parameters.

Early Stopping

If you have a validation set, you can use early stopping to find the optimal number of boosting rounds. Early stopping requires at least one set in `evals`. If there’s more than one, it will use the last.

```python
train(..., evals=evals, early_stopping_rounds=10)
```

The model will train until the validation score stops improving. Validation error needs to decrease at least every `early_stopping_rounds` to continue training.

If early stopping occurs, the model will have two additional fields: `bst.best_score`, `bst.best_iteration`. Note that `xgboost.train()` will return a model from the last iteration, not the best one.

This works with both metrics to minimize (RMSE, log loss, etc.) and to maximize (MAP, NDCG, AUC). Note that if you specify more than one evaluation metric the last one in `param['eval_metric']` is used for early stopping.
Prediction

A model that has been trained or loaded can perform predictions on data sets.

```python
# 7 entities, each contains 10 features
data = np.random.rand(7, 10)
dtest = xgb.DMatrix(data)
ypred = bst.predict(dtest)
```

If early stopping is enabled during training, you can get predictions from the best iteration with `bst.best_iteration`:

```python
ypred = bst.predict(dtest, iteration_range=(0, bst.best_iteration + 1))
```

Plotting

You can use plotting module to plot importance and output tree.

To plot importance, use `xgboost.plot_importance()`. This function requires `matplotlib` to be installed.

```python
xgb.plot_importance(bst)
```

To plot the output tree via `matplotlib`, use `xgboost.plot_tree()`, specifying the ordinal number of the target tree. This function requires `graphviz` and `matplotlib`.

```python
xgb.plot_tree(bst, num_trees=2)
```

When you use IPython, you can use the `xgboost.to_graphviz()` function, which converts the target tree to a `graphviz` instance. The `graphviz` instance is automatically rendered in IPython.

```python
xgb.to_graphviz(bst, num_trees=2)
```

Scikit-Learn interface

XGBoost provides an easy to use scikit-learn interface for some pre-defined models including regression, classification and ranking. See `Using the Scikit-Learn Estimator Interface` for more info.

```python
# Use "hist" for training the model.
reg = xgb.XGBRegressor(tree_method="hist", device="cuda")
# Fit the model using predictor X and response y.
reg.fit(X, y)
# Save model into JSON format.
reg.save_model("regressor.json")
```

User can still access the underlying booster model when needed:

```python
booster: xgb.Booster = reg.get_booster()
```
Using the Scikit-Learn Estimator Interface

Contents

- Overview
- Early Stopping
- Obtaining the native booster object
- Prediction
- Number of parallel threads

Overview

In addition to the native interface, XGBoost features a sklearn estimator interface that conforms to sklearn estimator guideline. It supports regression, classification, and learning to rank. Survival training for the sklearn estimator interface is still working in progress.

You can find some quick start examples at Collection of examples for using sklearn interface. The main advantage of using sklearn interface is that it works with most of the utilities provided by sklearn like sklearn.model_selection.cross_validate(). Also, many other libraries recognize the sklearn estimator interface thanks to its popularity.

With the sklearn estimator interface, we can train a classification model with only a couple lines of Python code. Here’s an example for training a classification model:

```python
from sklearn.datasets import load_breast_cancer
from sklearn.model_selection import train_test_split
import xgboost as xgb

X, y = load_breast_cancer(return_X_y=True)
X_train, X_test, y_train, y_test = train_test_split(X, y, stratify=y, random_state=94)

# Use "hist" for constructing the trees, with early stopping enabled.
clf = xgb.XGBClassifier(tree_method="hist", early_stopping_rounds=2)
# Fit the model, test sets are used for early stopping.
clf.fit(X_train, y_train, eval_set=[(X_test, y_test)])
# Save model into JSON format.
clf.save_model("clf.json")
```

The tree_method parameter specifies the method to use for constructing the trees, and the early_stopping_rounds parameter enables early stopping. Early stopping can help prevent overfitting and save time during training.
Early Stopping

As demonstrated in the previous example, early stopping can be enabled by the parameter `early_stopping_rounds`. Alternatively, there’s a callback function that can be used `xgboost.callback.EarlyStopping` to specify more details about the behavior of early stopping, including whether XGBoost should return the best model instead of the full stack of trees:

```python
early_stop = xgb.callback.EarlyStopping(
    rounds=2, metric_name='logloss', data_name='validation_0', save_best=True
)
clf = xgb.XGBClassifier(tree_method="hist", callbacks=[early_stop])
clf.fit(X_train, y_train, eval_set=[[X_test, y_test]])
```

At present, XGBoost doesn’t implement data splitting logic within the estimator and relies on the `eval_set` parameter of the `xgboost.XGBModel.fit()` method. If you want to use early stopping to prevent overfitting, you’ll need to manually split your data into training and testing sets using the `sklearn.model_selection.train_test_split()` function from the `sklearn` library. Some other machine learning algorithms, like those in `sklearn`, include early stopping as part of the estimator and may work with cross validation. However, using early stopping during cross validation may not be a perfect approach because it changes the model’s number of trees for each validation fold, leading to different model. A better approach is to retrain the model after cross validation using the best hyperparameters along with early stopping. If you want to experiment with idea of using cross validation with early stopping, here is a snippet to begin with:

```python
from sklearn.base import clone
from sklearn.datasets import load_breast_cancer
from sklearn.model_selection import StratifiedKFold, cross_validate
import xgboost as xgb

X, y = load_breast_cancer(return_X_y=True)

def fit_and_score(estimator, X_train, X_test, y_train, y_test):
    """Fit the estimator on the train set and score it on both sets""
    estimator.fit(X_train, y_train, eval_set=[[X_test, y_test]])
    train_score = estimator.score(X_train, y_train)
    test_score = estimator.score(X_test, y_test)
    return estimator, train_score, test_score

cv = StratifiedKFold(n_splits=5, shuffle=True, random_state=94)
clf = xgb.XGBClassifier(tree_method="hist", early_stopping_rounds=3)
results = {}

for train, test in cv.split(X, y):
    X_train = X[train]
    X_test = X[test]
    y_train = y[train]
    y_test = y[test]

(continues on next page)
est, train_score, test_score = fit_and_score(
    clone(clf), X_train, X_test, y_train, y_test
)
results[est] = (train_score, test_score)

Obtaining the native booster object

The sklearn estimator interface primarily facilitates training and doesn’t implement all features available in XGBoost. For instance, in order to have cached predictions, `xgboost.DMatrix` needs to be used with `xgboost.Booster.predict()`. One can obtain the booster object from the sklearn interface using `xgboost.XGBModel.get_booster()`:

```python
booster = clf.get_booster()
print(booster.num_boosted_rounds())
```

Prediction

When early stopping is enabled, prediction functions including the `xgboost.XGBModel.predict()`, `xgboost.XGBModel.score()`, and `xgboost.XGBModel.apply()` methods will use the best model automatically. Meaning the `xgboost.XGBModel.best_iteration` is used to specify the range of trees used in prediction.

To have cached results for incremental prediction, please use the `xgboost.Booster.predict()` method instead.

Number of parallel threads

When working with XGBoost and other sklearn tools, you can specify how many threads you want to use by using the `n_jobs` parameter. By default, XGBoost uses all the available threads on your computer, which can lead to some interesting consequences when combined with other sklearn functions like `sklearn.model_selection.cross_validate()`. If both XGBoost and sklearn are set to use all threads, your computer may start to slow down significantly due to something called “thread thrashing”. To avoid this, you can simply set the `n_jobs` parameter for XGBoost to `None` (which uses all threads) and the `n_jobs` parameter for sklearn to 1. This way, both programs will be able to work together smoothly without causing any unnecessary computer strain.

Python API Reference

This page gives the Python API reference of xgboost, please also refer to Python Package Introduction for more information about the Python package.
Global Configuration

`xgboost.config_context(**new_config)`

Context manager for global XGBoost configuration.

Global configuration consists of a collection of parameters that can be applied in the global scope. See Global Configuration for the full list of parameters supported in the global configuration.

**Note**

All settings, not just those presently modified, will be returned to their previous values when the context manager is exited. This is not thread-safe.

Added in version 1.4.0.

**Parameters**

`new_config (Dict[str, Any])` – Keyword arguments representing the parameters and their values

**Return type**

`Iterator[None]`

**Example**

```python
import xgboost as xgb

# Show all messages, including ones pertaining to debugging
xgb.set_config(verbosity=2)

# Get current value of global configuration
# This is a dict containing all parameters in the global configuration,
# including 'verbosity'
config = xgb.get_config()
assert config['verbosity'] == 2

# Example of using the context manager xgb.config_context().
# The context manager will restore the previous value of the global
# configuration upon exiting.
with xgb.config_context(verbosity=0):
    # Suppress warning caused by model generated with XGBoost version < 1.0.0
    bst = xgb.Booster(model_file='./old_model.bin')
assert xgb.get_config()['verbosity'] == 2  # old value restored
```

Nested configuration context is also supported:
Example

```python
with xgb.config_context(verbosity=3):
    assert xgb.get_config()['verbosity'] == 3
with xgb.config_context(verbosity=2):
    assert xgb.get_config()['verbosity'] == 2
xgb.set_config(verbosity=2)
assert xgb.get_config()['verbosity'] == 2
with xgb.config_context(verbosity=3):
    assert xgb.get_config()['verbosity'] == 3
```

See also

- `set_config`
  - Set global XGBoost configuration
- `get_config`
  - Get current values of the global configuration

**xgboost.set_config(**new_config**)**

Set global configuration.

Global configuration consists of a collection of parameters that can be applied in the global scope. See *Global Configuration* for the full list of parameters supported in the global configuration.

Added in version 1.4.0.

**Parameters**

- **new_config**(Dict[str, Any]) – Keyword arguments representing the parameters and their values

**Return type**

None

Example

```python
import xgboost as xgb

# Show all messages, including ones pertaining to debugging
xgb.set_config(verbosity=2)

# Get current value of global configuration
# This is a dict containing all parameters in the global configuration,
# including 'verbosity'
config = xgb.get_config()
assert config['verbosity'] == 2

# Example of using the context manager xgb.config_context().
# The context manager will restore the previous value of the global
# configuration upon exiting.
with xgb.config_context(verbosity=0):
```

(continues on next page)
# Suppress warning caused by model generated with XGBoost version < 1.0.0
bst = xgb.Booster(model_file='./old_model.bin')
assert xgb.get_config()['verbosity'] == 2  # old value restored

Nested configuration context is also supported:

```
with xgb.config_context(verbosity=3):
    assert xgb.get_config()['verbosity'] == 3
with xgb.config_context(verbosity=2):
    assert xgb.get_config()['verbosity'] == 2
xgb.set_config(verbosity=2)
assert xgb.get_config()['verbosity'] == 2
with xgb.config_context(verbosity=3):
    assert xgb.get_config()['verbosity'] == 3
```

**Example**

```
import xgb

# Show all messages, including ones pertaining to debugging
xgb.set_config(verbosity=2)

# Get current value of global configuration
# This is a dict containing all parameters in the global configuration,
# including 'verbosity'
config = xgb.get_config()
assert config['verbosity'] == 2

# Example of using the context manager xgb.config_context().
# The context manager will restore the previous value of the global
# configuration upon exiting.
with xgb.config_context(verbosity=0):
    # Suppress warning caused by model generated with XGBoost version < 1.0.0
    bst = xgb.Booster(model_file='./old_model.bin')
assert xgb.get_config()['verbosity'] == 2  # old value restored
```

**xgboost.get_config()**

Get current values of the global configuration.

Global configuration consists of a collection of parameters that can be applied in the global scope. See *Global Configuration* for the full list of parameters supported in the global configuration.

Added in version 1.4.0.

**Returns**

- **args** – The list of global parameters and their values

**Return type**

Dict[str, Any]

**Example**

```
import xgb

# Show all messages, including ones pertaining to debugging
xgb.set_config(verbosity=2)

# Get current value of global configuration
# This is a dict containing all parameters in the global configuration,
# including 'verbosity'
config = xgb.get_config()
assert config['verbosity'] == 2

# Example of using the context manager xgb.config_context().
# The context manager will restore the previous value of the global
# configuration upon exiting.
with xgb.config_context(verbosity=0):
    # Suppress warning caused by model generated with XGBoost version < 1.0.0
    bst = xgb.Booster(model_file='./old_model.bin')
assert xgb.get_config()['verbosity'] == 2  # old value restored
```
Nested configuration context is also supported:

**Example**

```python
with xgb.config_context(verbosity=3):
    assert xgb.get_config()]['verbosity'] == 3
with xgb.config_context(verbosity=2):
    assert xgb.get_config()]['verbosity'] == 2
xgb.set_config(verbosity=2)
assert xgb.get_config()]['verbosity'] == 2
with xgb.config_context(verbosity=3):
    assert xgb.get_config()]['verbosity'] == 3
```

**xgboost.build_info()**

Build information of XGBoost. The returned value format is not stable. Also, please note that build time dependency is not the same as runtime dependency. For instance, it’s possible to build XGBoost with older CUDA version but run it with the lastest one.

Added in version 1.6.0.

**Return type**

dict

**Core Data Structure**

Core XGBoost Library.

**class xgboost.DMatrix(data, label=None, *, weight=None, base_margin=None, missing=None, silent=False, feature_names=None, feature_types=None, nthread=None, group=None, qid=None, label_lower_bound=None, label_upper_bound=None, feature_weights=None, enable_categorical=False, data_split_mode=DataSplitMode.ROW)**

Bases: object

Data Matrix used in XGBoost.

DMatrix is an internal data structure that is used by XGBoost, which is optimized for both memory efficiency and training speed. You can construct DMatrix from multiple different sources of data.

**Parameters**

- **data** *(Any)* – Data source of DMatrix. See Supported data structures for various XGBoost functions for a list of supported input types.
- **label** *(Any | None)* – Label of the training data.
- **weight** *(Any | None)* – Weight for each instance.

**Note**

For ranking task, weights are per-group. In ranking task, one weight is assigned to each group (not each data point). This is because we only care about the relative ordering of data points within each group, so it doesn’t make sense to assign weights to individual data points.
• **base_margin** *(Any | None)* – Global bias for each instance. See **Intercept** for details.

• **missing** *(float | None)* – Value in the input data which needs to be present as a missing value. If None, defaults to np.nan.

• **silent** *(bool)* – Whether print messages during construction

• **feature_names** *(Sequence[str] | None)* – Set names for features.

• **feature_types** *(Sequence[str] | None)* – Set types for features. If *data* is a DataFrame type and passing *enable_categorical=True*, the types will be deduced automatically from the column types. Otherwise, one can pass a list-like input with the same length as number of columns in *data*, with the following possible values:

  – ”c”, which represents categorical columns.
  – ”q”, which represents numeric columns.
  – ”int”, which represents integer columns.
  – ”i”, which represents boolean columns.

Note that, while categorical types are treated differently from the rest for model fitting purposes, the other types do not influence the generated model, but have effects in other functionalities such as feature importances.

For categorical features, the input is assumed to be preprocessed and encoded by the users. The encoding can be done via `sklearn.preprocessing.OrdinalEncoder` or pandas dataframe `.cat.codes` method. This is useful when users want to specify categorical features without having to construct a dataframe as input.

• **nthread** *(int | None)* – Number of threads to use for loading data when parallelization is applicable. If -1, uses maximum threads available on the system.

• **group** *(Any | None)* – Group size for all ranking group.

• **qid** *(Any | None)* – Query ID for data samples, used for ranking.

• **label_lower_bound** *(Any | None)* – Lower bound for survival training.

• **label_upper_bound** *(Any | None)* – Upper bound for survival training.

• **feature_weights** *(Any | None)* – Set feature weights for column sampling.

• **enable_categorical** *(bool)* – Added in version 1.3.0.

---

**Note**

This parameter is experimental

Experimental support of specializing for categorical features.

If passing ‘True’ and ‘data’ is a data frame (from supported libraries such as Pandas, Modin or cuDF), columns of categorical types will automatically be set to be of categorical type (feature_type='c') in the resulting DMatrix.

If passing ‘False’ and ‘data’ is a data frame with categorical columns, it will result in an error being thrown.

If ‘data’ is not a data frame, this argument is ignored.

JSON/UBJSON serialization format is required for this.
• **data_split_mode** (*DataSplitMode*)

```python
data_split_mode()
```

Get the data split mode of the DMatrix.

Added in version 2.1.0.

**Return type**

`DataSplitMode`

**property feature_names**: `Sequence[str] | None`

Labels for features (column labels).

Setting it to `None` resets existing feature names.

**property feature_types**: `Sequence[str] | None`

Type of features (column types).

This is for displaying the results and categorical data support. See `DMatrix` for details.

Setting it to `None` resets existing feature types.

```python
get_base_margin()
```

Get the base margin of the DMatrix.

**Return type**

`base_margin`

```python
get_data()
```

Get the predictors from DMatrix as a CSR matrix. This getter is mostly for testing purposes. If this is a quantized DMatrix then quantized values are returned instead of input values.

Added in version 1.7.0.

**Return type**

`csr_matrix`

```python
get_float_info(field)
```

Get float property from the DMatrix.

**Parameters**

- `field (str)`: The field name of the information

**Returns**

- `info`: a numpy array of float information of the data

**Return type**

`array`

```python
get_group()
```

Get the group of the DMatrix.

**Return type**

`group`

```python
get_label()
```

Get the label of the DMatrix.

**Returns**

- `label`

**Return type**

`array`
get_quantile_cut()
Get quantile cuts for quantization.
Added in version 2.0.0.

Return type

Tuple[ndarray, ndarray]

get_uint_info(field)
Get unsigned integer property from the DMatrix.

Parameters

field (str) – The field name of the information

Returns

info – a numpy array of unsigned integer information of the data

Return type

array

get_weight()
Get the weight of the DMatrix.

Returns

weight

Return type

array

num_col()
Get the number of columns (features) in the DMatrix.

Return type

int

num_nonmissing()
Get the number of non-missing values in the DMatrix.
Added in version 1.7.0.

Return type

int

num_row()
Get the number of rows in the DMatrix.

Return type

int

save_binary(fname, silent=True)
Save DMatrix to an XGBoost buffer. Saved binary can be later loaded by providing the path to xgboost. DMatrix() as input.

Parameters

• fname (string or os.PathLike) – Name of the output buffer file.
  • silent (bool (optional; default: True)) – If set, the output is suppressed.

Return type

None
**set_base_margin** *(margin)*
Set base margin of booster to start from.

This can be used to specify a prediction value of existing model to be base_margin. However, remember margin is needed, instead of transformed prediction e.g. for logistic regression: need to put in value before logistic transformation see also example/demo.py

**Parameters**

- **margin** *(array like)* – Prediction margin of each datapoint

**Return type**
None

**set_float_info** *(field, data)*
Set float type property into the DMatrix.

**Parameters**

- **field** *(str)* – The field name of the information
- **data** *(numpy array)* – The array of data to be set

**Return type**
None

**set_float_info_npy2d** *(field, data)*
Set float type property into the DMatrix for numpy 2d array input

**Parameters**

- **field** *(str)* – The field name of the information
- **data** *(numpy array)* – The array of data to be set

**Return type**
None

**set_group** *(group)*
Set group size of DMatrix (used for ranking).

**Parameters**

- **group** *(array like)* – Group size of each group

**Return type**
None

**set_info**(*, label=None, weight=None, base_margin=None, group=None, qid=None, label_lower_bound=None, label_upper_bound=None, feature_names=None, feature_types=None, feature_weights=None)*
Set meta info for DMatrix. See doc string for `xgboost.DMatrix`.

**Parameters**

- **label** *(Any | None)*
- **weight** *(Any | None)*
- **base_margin** *(Any | None)*
- **group** *(Any | None)*
- **qid** *(Any | None)*
• label_lower_bound (Any | None)
• label_upper_bound (Any | None)
• feature_names (Sequence[str] | None)
• feature_types (Sequence[str] | None)
• feature_weights (Any | None)

Return type
None

set_label(label)
Set label of dmatrix

Parameters
label (array like) – The label information to be set into DMatrix

Return type
None

set_uint_info(field, data)
Set uint type property into the DMatrix.

Parameters
• field (str) – The field name of the information
• data (numpy array) – The array of data to be set

Return type
None

set_weight(weight)
Set weight of each instance.

Parameters
weight (array like) – Weight for each data point

Note
For ranking task, weights are per-group.
In ranking task, one weight is assigned to each group (not each data point). This is because we only care about the relative ordering of data points within each group, so it doesn’t make sense to assign weights to individual data points.

Return type
None

slice(rindex, allow_groups=False)
Slice the DMatrix and return a new DMatrix that only contains rindex.

Parameters
• rindex (List[int] | ndarray) – List of indices to be selected.
• allow_groups (bool) – Allow slicing of a matrix with a groups attribute

Returns
A new DMatrix containing only selected indices.
Return type

```python
class xgboost.QuantileDMatrix(data, label=None, *, weight=None, base_margin=None, missing=None, silent=False, feature_names=None, feature_types=None, nthread=None, max_bin=None, ref=None, group=None, qid=None, label_lower_bound=None, label_upper_bound=None, feature_weights=None, enable_categorical=False, data_split_mode=DataSplitMode.ROW)
```

Bases: `DMatrix`

A DMatrix variant that generates quantilized data directly from input for the hist tree method. This DMatrix is primarily designed to save memory in training by avoiding intermediate storage. Set `max_bin` to control the number of bins during quantisation, which should be consistent with the training parameter `max_bin`. When `QuantileDMatrix` is used for validation/test dataset, `ref` should be another `QuantileDMatrix` (or `DMatrix`, but not recommended as it defeats the purpose of saving memory) constructed from training dataset. See `xgboost.DMatrix` for documents on meta info.

**Note**

Do not use `QuantileDMatrix` as validation/test dataset without supplying a reference (the training dataset) `QuantileDMatrix` using `ref` as some information may be lost in quantisation.

Added in version 1.7.0.

**Parameters**

- `max_bin` (*int* / *None*) – The number of histogram bin, should be consistent with the training parameter `max_bin`.

- `ref` (*DMatrix* / *None*) – The training dataset that provides quantile information, needed when creating validation/test dataset with `QuantileDMatrix`. Supplying the training DMatrix as a reference means that the same quantisation applied to the training data is applied to the validation/test data.

- `data` (*Any*) – Data source of DMatrix. See Supported data structures for various XGBoost functions for a list of supported input types.

- `label` (*Any* / *None*) – Label of the training data.

- `weight` (*Any* / *None*) – Weight for each instance.

**Note**

For ranking task, weights are per-group. In ranking task, one weight is assigned to each group (not each data point). This is because we only care about the relative ordering of data points within each group, so it doesn’t make sense to assign weights to individual data points.

- `base_margin` (*Any* / *None*) – Global bias for each instance. See Intercept for details.

- `missing` (*float* / *None*) – Value in the input data which needs to be present as a missing value. If None, defaults to np.nan.

- `silent` (*bool*) – Whether print messages during construction

- `feature_names` (*Sequence[str]* / *None*) – Set names for features.
• **feature_types** *(Sequence[| Any ] | None)* – Set types for features. If `data` is a DataFrame type and passing `enable_categorical=True`, the types will be deduced automatically from the column types.

Otherwise, one can pass a list-like input with the same length as number of columns in `data`, with the following possible values:

- ”c”, which represents categorical columns.
- ”q”, which represents numeric columns.
- ”int”, which represents integer columns.
- ”i”, which represents boolean columns.

Note that, while categorical types are treated differently from the rest for model fitting purposes, the other types do not influence the generated model, but have effects in other functionalities such as feature importances.

For categorical features, the input is assumed to be preprocessed and encoded by the users. The encoding can be done via `sklearn.preprocessing.OrdinalEncoder` or pandas dataframe `.cat.codes` method. This is useful when users want to specify categorical features without having to construct a dataframe as input.

• **nthread** *(int | None)* – Number of threads to use for loading data when parallelization is applicable. If -1, uses maximum threads available on the system.

• **group** *(Any | None)* – Group size for all ranking group.

• **qid** *(Any | None)* – Query ID for data samples, used for ranking.

• **label_lower_bound** *(Any | None)* – Lower bound for survival training.

• **label_upper_bound** *(Any | None)* – Upper bound for survival training.

• **feature_weights** *(Any | None)* – Set feature weights for column sampling.

• **enable_categorical** *(bool)* – Added in version 1.3.0.

---

**Note**

This parameter is experimental

Experimental parameter support of specializing for categorical features.

If passing ‘True’ and ‘data’ is a data frame (from supported libraries such as Pandas, Modin or cuDF), columns of categorical types will automatically be set to be of categorical type (feature_type=’c’) in the resulting DMatrix.

If passing ‘False’ and ‘data’ is a data frame with categorical columns, it will result in an error being thrown.

If ‘data’ is not a data frame, this argument is ignored.

JSON/UBJSON serialization format is required for this.

• **data_split_mode** *(DataSplitMode)*

```python
class xgboost.Booster(params=None, cache=None, model_file=None)
Bases: object

A Booster of XGBoost.

Booster is the model of xgboost, that contains low level routines for training, prediction and evaluation.
```
Parameters

- **params** *(List | Dict[str, Any] | None)* – Parameters for boosters.
- **cache** *(Sequence[DMatrix] | None)* – List of cache items.
- **model_file** *(Booster | bytearray | PathLike | str | None)* – Path to the model file if it’s string or PathLike.

**attr**(key)

Get attribute string from the Booster.

**Parameters**

- **key** *(str)* – The key to get attribute from.

**Returns**

The attribute value of the key, returns None if attribute do not exist.

**Return type**

value

**attributes()**

Get attributes stored in the Booster as a dictionary.

**Returns**

result – Returns an empty dict if there’s no attributes.

**Return type**

dictionary of attribute_name: attribute_value pairs of strings.

**property best_iteration: int**

The best iteration during training.

**property best_score: float**

The best evaluation score during training.

**boost**(dtrain, iteration, grad, hess)

Boost the booster for one iteration with customized gradient statistics. Like `xgboost.Booster.update()`, this function should not be called directly by users.

**Parameters**

- **dtrain** *(DMatrix)* – The training DMatrix.
- **grad** *(Any)* – The first order of gradient.
- **hess** *(Any)* – The second order of gradient.
- **iteration** *(int)*

**Return type**

None

**copy()**

Copy the booster object.

**Returns**

A copied booster model

**Return type**

booster
dump_model(fout=fout, fmap='', with_stats=False, dump_format='text')
Dump model into a text or JSON file. Unlike save_model(), the output format is primarily used for visualization or interpretation, hence it’s more human readable but cannot be loaded back to XGBoost.

Parameters
• fout (str | PathLike) – Output file name.
• fmap (str | PathLike) – Name of the file containing feature map names.
• with_stats (bool) – Controls whether the split statistics are output.
• dump_format (str) – Format of model dump file. Can be ‘text’ or ‘json’.

Return type
None
eval(data, name='eval', iteration=0)
Evaluate the model on mat.

Parameters
• data (DMatrix) – The dmatrix storing the input.
• name (str) – The name of the dataset.
• iteration (int) – The current iteration number.

Returns
result – Evaluation result string.

Return type
str
eval_set(evals, iteration=0, feval=None, output_margin=True)
Evaluate a set of data.

Parameters
• evals (Sequence[ Tuple[DMatrix, str]]) – List of items to be evaluated.
• iteration (int) – Current iteration.
• feval (Callable[[ndarray, DMatrix], Tuple[str, float] | None) – Custom evaluation function.
• output_margin (bool)

Returns
result – Evaluation result string.

Return type
str

property feature_names: Sequence[str] | None
Feature names for this booster. Can be directly set by input data or by assignment.

property feature_types: Sequence[str] | None
Feature types for this booster. Can be directly set by input data or by assignment. See DMatrix for details.

get_dump(fmap='', with_stats=False, dump_format='text')
Returns the model dump as a list of strings. Unlike save_model(), the output format is primarily used for visualization or interpretation, hence it’s more human readable but cannot be loaded back to XGBoost.

Parameters
• **fmap** (*str / PathLike*) – Name of the file containing feature map names.
• **with_stats** (*bool*) – Controls whether the split statistics are output.
• **dump_format** (*str*) – Format of model dump. Can be ‘text’, ‘json’ or ‘dot’.

**Return type**

*List*[str]

**get_fscore**(*fmap="")

Get feature importance of each feature.

**Note**

Zero-importance features will not be included

Keep in mind that this function does not include zero-importance feature, i.e. those features that have not been used in any split conditions.

**Parameters**

• **fmap** (*str / PathLike*) – The name of feature map file

**Return type**

*Dict*[str, list]*[float]*

**get_score**(*fmap="", importance_type='weight')

Get feature importance of each feature. For tree model Importance type can be defined as:

• ‘weight’: the number of times a feature is used to split the data across all trees.
• ‘gain’: the average gain across all splits the feature is used in.
• ‘cover’: the average coverage across all splits the feature is used in.
• ‘total_gain’: the total gain across all splits the feature is used in.
• ‘total_cover’: the total coverage across all splits the feature is used in.

**Note**

For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

**Note**

Zero-importance features will not be included

Keep in mind that this function does not include zero-importance feature, i.e. those features that have not been used in any split conditions.

**Parameters**

• **fmap** (*str / PathLike*) – The name of feature map file.

• **importance_type** (*str*) – One of the importance types defined above.

**Returns**

• A map between feature names and their scores. When *gblinear* is used for
• multi-class classification the scores for each feature is a list with length 
n_classes, otherwise they’re scalars.

Return type
Dict[str, float | List[float]]

get_split_value_histogram(feature, fmap='', bins=None, as_pandas=True)

Get split value histogram of a feature

Parameters
• feature (str) – The name of the feature.
• fmap (PathLike | str) – The name of feature map file.
• bin – The maximum number of bins. Number of bins equals number of unique split values 
n_unique, if bins == None or bins > n_unique.
• as_pandas (bool) – Return pd.DataFrame when pandas is installed. If False or pandas is 
  not installed, return numpy ndarray.
• bins (int | None)

Returns
• a histogram of used splitting values for the specified feature
• either as numpy array or pandas DataFrame.

Return type
ndarray | DataFrame

inplace_predict(data, iteration_range=(0, 0), predict_type='value', missing=nan, validate_features=True, 
  base_margin=None, strict_shape=False)

Run prediction in-place when possible, Unlike predict() method, inplace prediction does not cache the 
prediction result.

Calling only inplace_predict in multiple threads is safe and lock free. But the safety does not hold 
when used in conjunction with other methods. E.g. you can’t train the booster in one thread and perform 
prediction in the other.

Note

If the device ordinal of the input data doesn’t match the one configured for the booster, data will be 
copied to the booster device.

```python
booster.set_param({"device": "cuda:0"})
booster.inplace_predict(cupy_array)
booster.set_param({"device": "cpu"})
booster.inplace_predict(numpy_array)
```

Added in version 1.1.0.

Parameters
• data (Any) – The input data.
• iteration_range (Tuple[int | integer, int | integer]) – See predict() for 
details.
xgboost, Release 2.1.1

- **predict_type** *(str)* –
  - `value` Output model prediction values.
  - `margin` Output the raw untransformed margin value.
- **missing** *(float)* – See `xgboost.DMatrix` for details.
- **validate_features** *(bool)* – See `xgboost.Booster.predict()` for details.
- **base_margin** *(Any | None)* – See `xgboost.DMatrix` for details.
  Added in version 1.4.0.
- **strict_shape** *(bool)* – See `xgboost.Booster.predict()` for details.
  Added in version 1.4.0.

**Returns**

- **prediction** – The prediction result. When input data is on GPU, prediction result is stored in a cupy array.

**Return type**

`numpy.ndarray/cupy.ndarray`

`load_config(config)`

Load configuration returned by `save_config`.

Added in version 1.0.0.

**Parameters**

- **config** *(str)*

**Return type**

None

`load_model(fname)`

Load the model from a file or a bytearray.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See *Model IO* for more info.

```python
model.load_model("model.json")
# or
model.load_model("model.ubj")
```

**Parameters**

- **fname** *(str | bytearray | PathLike)* – Input file name or memory buffer (see also `save_raw`)

**Return type**

None

`num_boosted_rounds()`

Get number of boosted rounds. For gblinear this is reset to 0 after serializing the model.

**Return type**

int
**num_features()**

Number of features in booster.

**Return type**

int

**predict**

```python
predict(data, output_margin=False, pred_leaf=False, pred_contribs=False, approx_contribs=False,
pred_interactions=False, validate_features=True, training=False, iteration_range=(0, 0),
strict_shape=False)
```

Predict with data. The full model will be used unless `iteration_range` is specified, meaning user have to either slice the model or use the `best_iteration` attribute to get prediction from best model returned from early stopping.

**Note**

See *Prediction* for issues like thread safety and a summary of outputs from this function.

**Parameters**

- **data (DMatrix)** – The dmatrix storing the input.
- **output_margin (bool)** – Whether to output the raw untransformed margin value.
- **pred_leaf (bool)** – When this option is on, the output will be a matrix of (nsample, ntrees) with each record indicating the predicted leaf index of each sample in each tree. Note that the leaf index of a tree is unique per tree, so you may find leaf 1 in both tree 1 and tree 0.
- **pred_contribs (bool)** – When this is True the output will be a matrix of size (nsample, nfeats + 1) with each record indicating the feature contributions (SHAP values) for that prediction. The sum of all feature contributions is equal to the raw untransformed margin value of the prediction. Note the final column is the bias term.
- **approx_contribs (bool)** – Approximate the contributions of each feature. Used when `pred_contribs` or `pred_interactions` is set to True. Changing the default of this parameter (False) is not recommended.
- **pred_interactions (bool)** – When this is True the output will be a matrix of size (nsample, nfeats + 1, nfeats + 1) indicating the SHAP interaction values for each pair of features. The sum of each row (or column) of the interaction values equals the corresponding SHAP value (from `pred_contribs`), and the sum of the entire matrix equals the raw untransformed margin value of the prediction. Note the last row and column correspond to the bias term.
- **validate_features (bool)** – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
- **training (bool)** – Whether the prediction value is used for training. This can effect dart booster, which performs dropouts during training iterations but use all trees for inference. If you want to obtain result with dropouts, set this parameter to `True`. Also, the parameter is set to true when obtaining prediction for custom objective function.

Added in version 1.0.0.

- **iteration_range (Tuple[int | integer, int | integer])** – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying `iteration_range=(10, 20)`, then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

Added in version 1.4.0.
• **strict_shape** *(bool)* – When set to True, output shape is invariant to whether classification is used. For both value and margin prediction, the output shape is \((n\_samples, n\_groups)\), \(n\_groups == 1\) when multi-class is not used. Default to False, in which case the output shape can be \((n\_samples, )\) if multi-class is not used.

  Added in version 1.4.0.

**Returns**

**prediction**

**Return type**

*numpy array*

**save_config()**

Output internal parameter configuration of Booster as a JSON string.

Added in version 1.0.0.

**Return type**

*str*

**save_model(fname)**

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See *Model IO* for more info.

```python
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

**Parameters**

- **fname** *(str | PathLike)* – Output file name

  **Return type**

  *None*

**save_raw**(raw_format='ubj')

Save the model to a in memory buffer representation instead of file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See *Model IO* for more info.

**Parameters**

- **raw_format** *(str)* – Format of output buffer. Can be *json*, *ubj* or *deprecated*.

  **Return type**

  An in memory buffer representation of the model

**set_attr(****kwargs***)**

Set the attribute of the Booster.

**Parameters**

- ****kwargs** *(Any | None)* – The attributes to set. Setting a value to None deletes an attribute.

  **Return type**

  *None*
set_param(params, value=None)

Set parameters into the Booster.

Parameters

- params (Dict | Iterable[Tuple[str, Any] | str]) – list of key,value pairs, dict of key to value or simply str key
- value (str | None) – value of the specified parameter, when params is str key

Return type

None
trees_to_dataframe(fmap='')

Parse a boosted tree model text dump into a pandas DataFrame structure.

This feature is only defined when the decision tree model is chosen as base learner (booster in {gbtree, dart}). It is not defined for other base learner types, such as linear learners (booster=gblinear).

Parameters

- fmap (str | PathLike) – The name of feature map file.

Return type

DataFrame

update(dtrain, iteration, fobj=None)

Update for one iteration, with objective function calculated internally. This function should not be called directly by users.

Parameters

- dtrain (DMatrix) – Training data.
- iteration (int) – Current iteration number.
- fobj (Callable[[ndarray, DMatrix], Tuple[ndarray, ndarray]] | None) – Customized objective function.

Return type

None
class xgboost.DataIter(cache_prefix=None, release_data=True)

Bases: ABC

The interface for user defined data iterator. The iterator facilitates distributed training, QuantileDMatrix, and external memory support using DMatrix. Most of time, users don’t need to interact with this class directly.

Note

The class caches some intermediate results using the data input (predictor X) as key. Don’t repeat the X for multiple batches with different meta data (like label), make a copy if necessary.

Parameters

- cache_prefix (str | None) – Prefix to the cache files, only used in external memory.
- release_data (bool) – Whether the iterator should release the data during iteration. Set it to True if the data transformation (converting data to np.float32 type) is memory intensive. Otherwise, if the transformation is computation intensive then we can keep the cache.
**get_callbacks** *(enable_categorical)*

Get callback functions for iterating in C. This is an internal function.

**Parameters**

- **enable_categorical** *(bool)*

**Return type**

Tuple[Callable, Callable]

**abstract next**(input_data)

Set the next batch of data.

**Parameters**

- **input_data** *(Callable)* – A function with same data fields like data, label with xgboost.DMatrix.

**Return type**

0 if there’s no more batch, otherwise 1.

**property proxy: _ProxyDMatrix**

Handle of DMatrix proxy.

**reraise()**

Reraise the exception thrown during iteration.

**Return type**

None

**abstract reset()**

Reset the data iterator. Prototype for user defined function.

**Return type**

None

---

**Learning API**

Training Library containing training routines.

**xgboost.train**(params, dtrain, num_boost_round=10, *, evals=None, obj=None, feval=None, maximize=None, early_stopping_rounds=None, evals_result=None, verbose_eval=True, xgb_model=None, callbacks=None, custom_metric=None)

Train a booster with given parameters.

**Parameters**

- **params** *(Dict[str, Any]*) – Booster params.
- **dtrain** *(DMatrix)* – Data to be trained.
- **num_boost_round** *(int)* – Number of boosting iterations.
- **evals** *(Sequence[Tuple[DMatrix, str]] | None)* – List of validation sets for which metrics will be evaluated during training. Validation metrics will help us track the performance of the model.
- **obj** *(Callable[[ndarray, DMatrix], Tuple[ndarray, ndarray]] | None)* – Custom objective function. See Custom Objective for details.
- **feval** *(Callable[[ndarray, DMatrix], Tuple[str, float]] | None)* – Deprecated since version 1.6.0: Use custom_metric instead.
"maximize (bool | None) – Whether to maximize feval.

• **early_stopping_rounds** (int | None) – Activates early stopping. Validation metric needs to improve at least once in every early_stopping_rounds round(s) to continue training. Requires at least one item in evals. The method returns the model from the last iteration (not the best one). Use custom callback or model slicing if the best model is desired. If there’s more than one item in evals, the last entry will be used for early stopping. If there’s more than one metric in the eval_metric parameter given in params, the last metric will be used for early stopping. If early stopping occurs, the model will have two additional fields: bst.best_score, bst.best_iteration.

• **evals_result** (Dict[str, Dict[str, List[float] | List[Tuple[float, float]]]] | None) – This dictionary stores the evaluation results of all the items in watchlist.

Example: with a watchlist containing [(dtest, 'eval'), (dtrain, 'train')] and a parameter containing ('eval_metric': 'logloss'), the evals_result returns

```
{'train': {'logloss': ['0.48253', '0.35953']},
'eval': {'logloss': ['0.480385', '0.357756']}}
```

• **verbose_eval** (bool | int | None) – Requires at least one item in evals. If verbose_eval is True then the evaluation metric on the validation set is printed at each boosting stage. If verbose_eval is an integer then the evaluation metric on the validation set is printed at every given verbose_eval boosting stage. The last boosting stage / the boosting stage found by using early_stopping_rounds is also printed. Example: with verbose_eval=4 and at least one item in evals, an evaluation metric is printed every 4 boosting stages, instead of every boosting stage.

• **xgb_model** (str | PathLike | Booster | bytearray | None) – Xgb model to be loaded before training (allows training continuation).

• **callbacks** (Sequence[TrainingCallback] | None) – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using Callback API.

### Note

States in callback are not preserved during training, which means callback objects can not be reused for multiple training sessions without reinitialization or deepcopy.

```
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    xgboost.train(params, Xy, callbacks=callbacks)
```

• **custom_metric** (Callable[[ndarray, DMatrix], Tuple[str, float]] | None) – Custom metric function. See Custom Metric for details.

Returns

Booster

Return type

a trained booster model

```
xgboost.cv(params, dtrain, num_boost_round=10, nfold=3, stratified=False, folds=None, metrics=(), obj=None, feval=None, maximize=None, early_stopping_rounds=None, fpreproc=None, as_pandas=True, verbose_eval=None, show_stdv=True, seed=0, callbacks=None, shuffle=True, custom_metric=None)
```
Cross-validation with given parameters.

Parameters

- **params** (*dict*) – Booster params.
- **dtrain** (*DMatrix*) – Data to be trained.
- **num_boost_round** (*int*) – Number of boosting iterations.
- **nfold** (*int*) – Number of folds in CV.
- **stratified** (*bool*) – Perform stratified sampling.
- **folds** (*a KFold or StratifiedKFold instance or list of fold indices*) – Sklearn KFolds or StratifiedKFolds object. Alternatively may explicitly pass sample indices for each fold. For n folds, folds should be a length n list of tuples. Each tuple is (in, out) where in is a list of indices to be used as the training samples for the n-th fold and out is a list of indices to be used as the testing samples for the n-th fold.
- **metrics** (*string or list of strings*) – Evaluation metrics to be watched in CV.
- **obj** (*Callable[[ndarray, DMatrix], Tuple[ndarray, ndarray]] | None*) – Custom objective function. See Custom Objective for details.
- **feval** (*function*) – Deprecated since version 1.6.0: Use custom_metric instead.
- **maximize** (*bool*) – Whether to maximize feval.
- **early_stopping_rounds** (*int*) – Activates early stopping. Cross-Validation metric (average of validation metric computed over CV folds) needs to improve at least once in every early_stopping_rounds round(s) to continue training. The last entry in the evaluation history will represent the best iteration. If there’s more than one metric in the eval_metric parameter given in params, the last metric will be used for early stopping.
- **fpreproc** (*function*) – Preprocessing function that takes (dtrain, dtest, param) and returns transformed versions of those.
- **as_pandas** (*bool, default True*) – Return pd.DataFrame when pandas is installed. If False or pandas is not installed, return np.ndarray
- **verbose_eval** (*bool, int, or None, default None*) – Whether to display the progress. If None, progress will be displayed at every boosting stage. If an integer is given, progress will be displayed at every given verbose_eval boosting stage.
- **show_stdv** (*bool, default True*) – Whether to display the standard deviation in progress. Results are not affected, and always contains std.
- **seed** (*int*) – Seed used to generate the folds (passed to numpy.random.seed).
- **callbacks** (*Sequence[TrainingCallback] | None*) – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using Callback API.

Note

States in callback are not preserved during training, which means callback objects can not be reused for multiple training sessions without reinitialization or deepcopy.
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    xgboost.train(params, Xy, callbacks=callbacks)

- **shuffle** *(bool)* – Shuffle data before creating folds.
- **custom_metric** *(Callable[[ndarray, DMatrix], Tuple[str, float]] | None)*
  – Custom metric function. See *Custom Metric* for details.

**Returns**

evaluation history

**Return type**

list(string)

**Scikit-Learn API**

Scikit-Learn Wrapper interface for XGBoost.

```python
class xgboost.XGBRegressor(*, objective='reg:squarederror', **kwargs)
    Bases: XGBModel, RegressorMixin
```

Implementation of the scikit-learn API for XGBoost regression. See *Using the Scikit-Learn Estimator Interface* for more information.

**Parameters**

- **n_estimators** *(Optional[int])* – Number of gradient boosted trees. Equivalent to number of boosting rounds.
- **max_depth** *(Optional[int])* – Maximum tree depth for base learners.
- **max_leaves** *(Optional[int])* – Maximum number of leaves; 0 indicates no limit.
- **max_bin** *(Optional[int])* – If using histogram-based algorithm, maximum number of bins per feature
- **grow_policy** *(Optional[str])* – Tree growing policy.
  - depthwise: Favors splitting at nodes closest to the node,
  - lossguide: Favors splitting at nodes with highest loss change.
- **learning_rate** *(Optional[float])* – Boosting learning rate (xgb’s “eta”)
- **verbosity** *(Optional[int])* – The degree of verbosity. Valid values are 0 (silent) - 3 (debug).
- **objective** *(Union[str, xgboost.sklearn._SklObjWProto, Callable[[Any, Any], Tuple[numpy.ndarray, numpy.ndarray]], NoneType]*) – Specify the learning task and the corresponding learning objective or a custom objective function to be used.

For custom objective, see *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information, along with the end note for function signatures.

- **booster** *(Optional[str])* – Specify which booster to use: gbtree, gblinear or dart.
- **tree_method** *(Optional[str])* – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available. It’s recommended to study this option from the parameters document *tree method*
• **n_jobs** (*Optional*[int]) – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.

• **gamma** (*Optional*[float]) – (min_split_loss) Minimum loss reduction required to make a further partition on a leaf node of the tree.

• **min_child_weight** (*Optional*[float]) – Minimum sum of instance weight(hessian) needed in a child.

• **max_delta_step** (*Optional*[float]) – Maximum delta step we allow each tree’s weight estimation to be.

• **subsample** (*Optional*[float]) – Subsample ratio of the training instance.

• **sampling_method** (*Optional*[str]) – Sampling method. Used only by the GPU version of hist tree method.
  – uniform: Select random training instances uniformly.
  – gradient_based: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)

• **colsample_bytree** (*Optional*[float]) – Subsample ratio of columns when constructing each tree.

• **colsample_bylevel** (*Optional*[float]) – Subsample ratio of columns for each level.

• **colsample_bynode** (*Optional*[float]) – Subsample ratio of columns for each split.

• **reg_alpha** (*Optional*[float]) – L1 regularization term on weights (xgb’s alpha).

• **reg_lambda** (*Optional*[float]) – L2 regularization term on weights (xgb’s lambda).

• **scale_pos_weight** (*Optional*[float]) – Balancing of positive and negative weights.

• **base_score** (*Optional*[float]) – The initial prediction score of all instances, global bias.

• **random_state** (*Union*[numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType]) – Random number seed.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.</td>
</tr>
</tbody>
</table>

• **missing** (float) – Value in the data which needs to be present as a missing value. Default to numpy.nan.

• **num_parallel_tree** (*Optional*[int]) – Used for boosting random forest.

• **monotone_constraints** (*Union*[Dict[str, int], str, NoneType]) – Constraint of variable monotonicity. See tutorial for more information.

• **interaction_constraints** (*Union*[str, List[Tuple[str]], NoneType]) – Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nested list, e.g. `[[0, 1], [2, 3, 4]]`, where each inner list is a group of indices of features that are allowed to interact with each other. See tutorial for more information.
• **importance_type** *(Optional[str]*) – The feature importance type for the feature_importances_ property:
  - For tree model, it’s either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  - For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

• **device** *(Optional[str]*) – Added in version 2.0.0.
  Device ordinal, available options are *cpu*, *cuda*, and *gpu*.

• **validate_parameters** *(Optional[bool]*) – Give warnings for unknown parameter.

• **enable_categorical** *(bool)* – See the same parameter of *DMatrix* for details.

• **feature_types** *(Optional[Sequence[str]*) – Added in version 1.7.0.
  Used for specifying feature types without constructing a dataframe. See *DMatrix* for details.

• **max_cat_to_onehot** *(Optional[int]*) – Added in version 1.6.0.

**Note**
This parameter is experimental

A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, *enable_categorical* needs to be set to have categorical feature support. See *Categorical Data* and *Parameters for Categorical Feature* for details.

• **max_cat_threshold** *(Optional[int]*) – Added in version 1.7.0.

**Note**
This parameter is experimental

Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, *enable_categorical* needs to be set to have categorical feature support. See *Categorical Data* and *Parameters for Categorical Feature* for details.

• **multi_strategy** *(Optional[str]*) – Added in version 2.0.0.

**Note**
This parameter is working-in-progress.

The strategy used for training multi-target models, including multi-target regression and multi-class classification. See *Multiple Outputs* for more information.
  - one_output_per_tree: One model for each target.
  - multi_output_tree: Use multi-target trees.

• **eval_metric** *(Union[str, List[str], Callable, NoneType]*) – Added in version 1.6.0.
Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in sklearn.metrics, or any other user defined metric that looks like sklearn.metrics.

If custom objective is also provided, then custom metric should implement the corresponding reverse link function.

Unlike the `scoring` parameter commonly used in scikit-learn, when a callable object is provided, it's assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

For advanced usage on Early stopping like directly choosing to maximize instead of minimize, see `xgboost.callback.EarlyStopping`.

See Custom Objective and Evaluation Metric and Custom objective and metric for more information.

```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

- `early_stopping_rounds (Optional[int])` – Added in version 1.6.0.
  - Activates early stopping. Validation metric needs to improve at least once in every `early_stopping_rounds` round(s) to continue training. Requires at least one item in `eval_set` in `fit()`.
  - If early stopping occurs, the model will have two additional attributes: `best_score` and `best_iteration`. These are used by the `predict()` and `apply()` methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the `iteration_range` in these inference methods. In addition, other utilities like model plotting can also use the entire model.
  - If you prefer to discard the trees after `best_iteration`, consider using the callback function `xgboost.callback.EarlyStopping`.
  - If there’s more than one item in `eval_set`, the last entry will be used for early stopping. If there’s more than one metric in `eval_metric`, the last metric will be used for early stopping.

- `callbacks (Optional[List[xgboost.callback.TrainingCallback]])` – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using `Callback API`.

- **Note**

  States in callback are not preserved during training, which means callback objects cannot be reused for multiple training sessions without reinitialization or deep-copy.

```python
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
```
reg = xgboost.XGBRegressor(**params, callbacks=callbacks)
reg.fit(X, y)

- **kwargs (Optional[Any]) – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found here. Attempting to set a parameter via the constructor args and **kwargs dict simultaneously will result in a TypeError.

** Note

**kwargs unsupported by scikit-learn

**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed via this argument will interact properly with scikit-learn.

** Note

Custom objective function

A custom objective function can be provided for the objective parameter. In this case, it should have the signature `objective(y_true, y_pred) -> [grad, hess]` or `objective(y_true, y_pred, *, sample_weight) -> [grad, hess]`:

- y_true: array_like of shape [n_samples]
  The target values
- y_pred: array_like of shape [n_samples]
  The predicted values
- sample_weight :
  Optional sample weights.
- grad: array_like of shape [n_samples]
  The value of the gradient for each sample point.
- hess: array_like of shape [n_samples]
  The value of the second derivative for each sample point

** apply**(X, iteration_range=None)**

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then `best_iteration` is used automatically.

** Parameters

- X (array_like, shape=[n_samples, n_features]) – Input features matrix.
- iteration_range (Tuple[int | integer, int | integer] | None) – See `predict()`.

** Returns

- X_leaves – For each datapoint x in X and for each tree, return the index of the leaf x ends up in. Leaves are numbered within [0; 2**(self.max_depth+1)], possibly with gaps in the numbering.

** Return type

array_like, shape=[n_samples, n_trees]
property **best_iteration**: int

The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is the first round, then best_iteration is 0.

property **best_score**: float

The best score obtained by early stopping.

property **coef_**: ndarray

Coefficients property

---

**Note**

Coefficients are defined only for linear learners

Coefficients are only defined when the linear model is chosen as base learner (booster=gblinear). It is not defined for other base learner types, such as tree learners (booster=gbtree).

Returns

coef_

Return type

array of shape [n_features] or [n_classes, n_features]

**evals_result()**

Return the evaluation results.

If **eval_set** is passed to the **fit()** function, you can call **evals_result()** to get evaluation results for all passed **eval_sets**. When **eval_metric** is also passed to the **fit()** function, the **evals_result** will contain the **eval_metrics** passed to the **fit()** function.

The returned evaluation result is a dictionary:

```python
{'validation_0': {'logloss': ['0.604835', '0.531479']},
 'validation_1': {'logloss': ['0.41965', '0.17686']}}
```

Return type

evals_result

property **feature_importances_**: ndarray

Feature importances property, return depends on importance_type parameter. When model trained with multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “average” is defined based on the importance type. For instance, if the importance type is “total_gain”, then the score is sum of loss change for each split from all trees.

Returns

• **feature_importances_** (array of shape [n_features] except for multi-class)

• linear model, which returns an array with shape (n_features, n_classes)

property **feature_names_in_**: ndarray

Names of features seen during **fit()**. Defined only when X has feature names that are all strings.

**fit(X, y, *, sample_weight=None, base_margin=None, eval_set=None, verbose=True, xgb_model=None, sample_weight_eval_set=None, base_margin_eval_set=None, feature_weights=None)**
Fit gradient boosting model.

Note that calling `fit()` multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass `xgb_model` argument.

**Parameters**

- **X** *(Any)* – Feature matrix. See [Supported data structures for various XGBoost functions](#) for a list of supported types.

  When the `tree_method` is set to `hist`, internally, the `QuantileDMatrix` will be used instead of the `DMatrix` for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a numpy array on CPU but cuda is used for training, then the data is first processed on CPU then transferred to GPU.

- **y** *(Any)* – Labels

- **sample_weight** *(Any | None)* – instance weights

- **base_margin** *(Any | None)* – Global bias for each instance. See [Intercept](#) for details.

- **eval_set** *(Sequence[Tuple[Any, Any]] | None)* – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.

- **verbose** *(bool | int | None)* – If `verbose` is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If `verbose` is an integer, the evaluation metric is printed at each `verbose` boosting stage. The last boosting stage / the boosting stage found by using `early_stopping_rounds` is also printed.

- **xgb_model** *(Booster | XGBModel | str | None)* – file name of stored XGBoost model or ‘Booster’ instance XGBoost model to be loaded before training (allows training continuation).

- **sample_weight_eval_set** *(Sequence[Any] | None)* – A list of the form [L_1, L_2, …, L_n], where each L_i is an array like object storing instance weights for the i-th validation set.

- **base_margin_eval_set** *(Sequence[Any] | None)* – A list of the form [M_1, M_2, …, M_n], where each M_i is an array like object storing base margin for the i-th validation set.

- **feature_weights** *(Any | None)* – Weight for each feature, defines the probability of each feature being selected when `colsample` is being used. All values must be greater than 0, otherwise a `ValueError` is thrown.

**Return type**

`XGBModel`

**get_booster()**

Get the underlying xgboost Booster of this model.

This will raise an exception when `fit` was not called

**Returns**

`booster`

**Return type**

a xgboost booster of underlying model
get_metadata_routing()
Get metadata routing of this object.

Please check User Guide on how the routing mechanism works.

Returns
routing – A MetadataRequest encapsulating routing information.

Return type
MetadataRequest

get_num_boosting_rounds()
Gets the number of xgboost boosting rounds.

Return type
int

get_params(deep=True)
Get parameters.

Parameters
dee (bool)

Return type
Dict[str, Any]

get_xgb_params()
Get xgboost specific parameters.

Return type
Dict[str, Any]

property intercept_: ndarray
Intercept (bias) property

For tree-based model, the returned value is the base_score.

Returns
intercept_

Return type
array of shape (1,) or [n_classes]

load_model(fname)
Load the model from a file or a bytearray.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

model.load_model("model.json")
# or
model.load_model("model.ubj")

Parameters
fname (str | bytearray | PathLike) – Input file name or memory buffer(see also save_raw)

Return type
None
**property n_features_in_:** int

Number of features seen during `fit()`.

**predict**(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)

Predict with X. If the model is trained with early stopping, then `best_iteration` is used automatically. The estimator uses `inplace_predict` by default and falls back to using `DMatrix` if devices between the data and the estimator don’t match.

### Note

This function is only thread safe for `gbtree` and `dart`.

**Parameters**

- **X** *(Any)* – Data to predict with.
- **output_margin** *(bool)* – Whether to output the raw untransformed margin value.
- **validate_features** *(bool)* – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
- **base_margin** *(Any | None)* – Global bias for each instance. See `Intercept` for details.
- **iteration_range** *(Tuple[int | integer, int | integer] | None)* – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying `iteration_range=(10, 20)`, then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

Added in version 1.4.0.

**Return type**

prediction

**save_model**(fname)

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See `Model IO` for more info.

```python
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

**Parameters**

- **fname** *(str | PathLike)* – Output file name

**Return type**

None

**score**(X, y, sample_weight=None)

Return the coefficient of determination of the prediction.

The coefficient of determination $R^2$ is defined as $1 - \frac{u}{v}$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).\text{sum()}$ and $v$ is the total sum of squares $((y_{true} - y_{true}.\text{mean}())^2).\text{sum()}$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse).
A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** (*array-like of shape (n_samples, n_features)*) – Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** (*array-like of shape (n_samples,) or (n_samples, n_outputs)*) – True values for $X$.

- **sample_weight** (*array-like of shape (n_samples,), default=None*) – Sample weights.

**Returns**

- **score** – $R^2$ of self.predict(X) w.r.t. y.

**Return type**

float

**Notes**

The $R^2$ score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score(). This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

**set_fit_request** (*, base_margin='UNCHANGED$', base_margin_eval_set='UNCHANGED$',
 eval_set='UNCHANGED$', feature_weights='UNCHANGED$',
 sample_weight='UNCHANGED$', sample_weight_eval_set='UNCHANGED$,
 verbose='UNCHANGED$', xgb_model='UNCHANGED$)

Request metadata passed to the fit method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to fit if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to fit.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.
Parameters

- **base_margin** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in fit.*

- **base_margin_eval_set** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin_eval_set parameter in fit.*

- **eval_set** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for eval_set parameter in fit.*

- **feature_weights** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for feature_weights parameter in fit.*

- **sample_weight** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight parameter in fit.*

- **sample_weight_eval_set** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight_eval_set parameter in fit.*

- **verbose** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for verbose parameter in fit.*

- **xgb_model** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for xgb_model parameter in fit.*

- **self**(XGBRegressor)

Returns

self – The updated object.

Return type

object

**set_params(**params)**

Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

Return type

self

Parameters

- **params** *(Any)*

**set_predict_request(***, base_margin='UNCHANGED', iteration_range='UNCHANGED', output_margin='UNCHANGED', validate_features='UNCHANGED'***)

Request metadata passed to the predict method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:
• True: metadata is requested, and passed to predict if provided. The request is ignored if metadata is not provided.
• False: metadata is not requested and the meta-estimator will not pass it to predict.
• None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
• str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

**Parameters**

- **base_margin** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for base_margin parameter in predict.
- **iteration_range** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for iteration_range parameter in predict.
- **output_margin** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for output_margin parameter in predict.
- **validate_features** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for validate_features parameter in predict.
- **self** *(XGBRegressor)*

**Returns**

self – The updated object.

**Return type**

object

**set_score_request(***, sample_weight='UNCHANGED'***)

Request metadata passed to the score method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- True: metadata is requested, and passed to score if provided. The request is ignored if metadata is not provided.
- False: metadata is not requested and the meta-estimator will not pass it to score.
- None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
• **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (`sklearn.utils.metadata_routing.UNCHANGED`) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

---

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a `Pipeline`. Otherwise it has no effect.

---

**Parameters**

- **sample_weight** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for `sample_weight` parameter in `score`.
- **self** *(XGBRegressor)*

**Returns**

**self** – The updated object.

**Return type**

**object**

---

**class** `xgboost.XGBClassifier(*, objective='binary:logistic', **kwargs)`

**Bases:** `XGBModel`, `ClassifierMixin`

Implementation of the scikit-learn API for XGBoost classification. See *Using the Scikit-Learn Estimator Interface* for more information.

**Parameters**

- **n_estimators** *(Optional[int]*) – Number of boosting rounds.
- **max_depth** *(Optional[int]*) – Maximum tree depth for base learners.
- **max_leaves** *(Optional[int]*) – Maximum number of leaves; 0 indicates no limit.
- **max_bin** *(Optional[int]*) – If using histogram-based algorithm, maximum number of bins per feature
- **grow_policy** *(Optional[str]*) – Tree growing policy.
  - depthwise: Favors splitting at nodes closest to the node,
  - lossguide: Favors splitting at nodes with highest loss change.
- **learning_rate** *(Optional[float]*) – Boosting learning rate (xgb’s “eta”)
- **verbosity** *(Optional[int]*) – The degree of verbosity. Valid values are 0 (silent) - 3 (debug).
- **objective** *(Union[str, xgboost.sklearn._SklObjWProto, Callable[[Any, Any], Tuple[numpy.ndarray, numpy.ndarray]], NoneType]*) – Specify the learning task and the corresponding learning objective or a custom objective function to be used.

For custom objective, see *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information, along with the end note for function signatures.
booster (Optional[str]) – Specify which booster to use: gbtree, gblinear or dart.

• tree_method (Optional[str]) – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available. It’s recommended to study this option from the parameters document tree method.

• n_jobs (Optional[int]) – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.

• gamma (Optional[float]) – (min_split_loss) Minimum loss reduction required to make a further partition on a leaf node of the tree.

• min_child_weight (Optional[float]) – Minimum sum of instance weight(hessian) needed in a child.

• max_delta_step (Optional[float]) – Maximum delta step we allow each tree’s weight estimation to be.

• subsample (Optional[float]) – Subsample ratio of the training instance.

• sampling_method (Optional[str]) – Sampling method. Used only by the GPU version of hist tree method.
  – uniform: Select random training instances uniformly.
  – gradient_based: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)

• colsample_bytree (Optional[float]) – Subsample ratio of columns when constructing each tree.

• colsample_bylevel (Optional[float]) – Subsample ratio of columns for each level.

• colsample_bynode (Optional[float]) – Subsample ratio of columns for each split.

• reg_alpha (Optional[float]) – L1 regularization term on weights (xgb’s alpha).

• reg_lambda (Optional[float]) – L2 regularization term on weights (xgb’s lambda).

• scale_pos_weight (Optional[float]) – Balancing of positive and negative weights.

• base_score (Optional[float]) – The initial prediction score of all instances, global bias.

• random_state (Union[numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType]) – Random number seed.

Note

Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.

• missing (float) – Value in the data which needs to be present as a missing value. Default to numpy.nan.

• num_parallel_tree (Optional[int]) – Used for boosting random forest.

• monotone_constraints (Union[Dict[str, int], str, NoneType]) – Constraint of variable monotonicity. See tutorial for more information.

• interaction_constraints (Union[str, List[Tuple[str]], NoneType]) – Constraints for interaction representing permitted interactions. The constraints must be specified
in the form of a nested list, e.g. `[[0, 1], [2, 3, 4]]`, where each inner list is a group of indices of features that are allowed to interact with each other. See tutorial for more information

- **importance_type** (*Optional*[str]) – The feature importance type for the feature_importances_ property:
  - For tree model, it’s either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  - For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

- **device** (*Optional*[str]) – Added in version 2.0.0.
  Device ordinal, available options are cpu, cuda, and gpu.

- **validate_parameters** (*Optional*[bool]) – Give warnings for unknown parameter.

- **enable_categorical** (bool) – See the same parameter of DMatrix for details.

- **feature_types** (*Optional*[Sequence[st]]) – Added in version 1.7.0.
  Used for specifying feature types without constructing a dataframe. See DMatrix for details.

- **max_cat_to_onehot** (*Optional*[int]) – Added in version 1.6.0.
  A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, enable_categorical needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

- **max_cat_threshold** (*Optional*[int]) – Added in version 1.7.0.
  Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, enable_categorical needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

- **multi_strategy** (*Optional*[str]) – Added in version 2.0.0.
  The strategy used for training multi-target models, including multi-target regression and multi-class classification. See Multiple Outputs for more information.
  - one_output_per_tree: One model for each target.
  - multi_output_tree: Use multi-target trees.
• **eval_metric** *(Union[str, List[str], Callable, NoneType]) – Added in version 1.6.0.*

Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in sklearn.metrics, or any other user defined metric that looks like sklearn.metrics.

If custom objective is also provided, then custom metric should implement the corresponding reverse link function.

Unlike the *scoring* parameter commonly used in scikit-learn, when a callable object is provided, it’s assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

For advanced usage on Early stopping like directly choosing to maximize instead of minimize, see `xgboost.callback.EarlyStopping`.

See *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information.

```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

• **early_stopping_rounds** *(Optional[int]) – Added in version 1.6.0.*

  - Activates early stopping. Validation metric needs to improve at least once in every early_stopping_rounds round(s) to continue training. Requires at least one item in eval_set in fit().

  - If early stopping occurs, the model will have two additional attributes: best_score and best_iteration. These are used by the predict() and apply() methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the iteration_range in these inference methods. In addition, other utilities like model plotting can also use the entire model.

  - If you prefer to discard the trees after best_iteration, consider using the callback function `xgboost.callback.EarlyStopping`.

  - If there’s more than one item in eval_set, the last entry will be used for early stopping. If there’s more than one metric in eval_metric, the last metric will be used for early stopping.

• **callbacks** *(Optional[List[xgboost.callback.TrainingCallback]]) – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using Callback API.*

**Note**

States in callback are not preserved during training, which means callback objects can not be reused for multiple training sessions without reinitialization or deepcopy.
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    reg = xgb.XGBRegressor(**params, callbacks=callbacks)
    reg.fit(X, y)

- **kwargs (Optional[Any]) – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found here. Attempting to set a parameter via the constructor args and **kwargs dict simultaneously will result in a TypeError.

** Note

**kwargs unsupported by scikit-learn

**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed via this argument will interact properly with scikit-learn.

** Note

Custom objective function

A custom objective function can be provided for the objective parameter. In this case, it should have the signature objective(y_true, y_pred) -> [grad, hess] or objective(y_true, y_pred, *, sample_weight) -> [grad, hess]:

y_true: array_like of shape [n_samples]
    The target values

y_pred: array_like of shape [n_samples]
    The predicted values

sample_weight:
    Optional sample weights.

grad: array_like of shape [n_samples]
    The value of the gradient for each sample point.

hess: array_like of shape [n_samples]
    The value of the second derivative for each sample point

** apply(X, iteration_range=None)

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then best_iteration is used automatically.

Parameters

- X (array_like, shape=[n_samples, n_features]) – Input features matrix.
- iteration_range (Tuple[int | integer, int | integer] | None) – See predict().

Returns

X_leaves – For each datapoint x in X and for each tree, return the index of the leaf x ends up in. Leaves are numbered within [0; 2**(self.max_depth+1)], possibly with gaps in the numbering.
**Return type**

array_like, shape=[n_samples, n_trees]

**property best_iteration:** int

The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is the first round, then best_iteration is 0.

**property best_score:** float

The best score obtained by early stopping.

**property coef:** ndarray

Coefficients property

---

**Note**

Coefficients are defined only for linear learners

Coefficients are only defined when the linear model is chosen as base learner (booster=gblinear). It is not defined for other base learner types, such as tree learners (booster=gbtree).

**Returns**

coef

**Return type**

array of shape [n_features] or [n_classes, n_features]

**evals_result()**

Return the evaluation results.

If eval_set is passed to the fit() function, you can call evals_result() to get evaluation results for all passed eval_sets. When eval_metric is also passed to the fit() function, the evals_result will contain the eval_metrics passed to the fit() function.

The returned evaluation result is a dictionary:

```python
{'validation_0': {'logloss': ['0.604835', '0.531479']},
 'validation_1': {'logloss': ['0.41965', '0.17686']}}
```

**Return type**

evals_result

**property feature_importances:** ndarray

Feature importances property, return depends on importance_type parameter. When model trained with multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “average” is defined based on the importance type. For instance, if the importance type is “total_gain”, then the score is sum of loss change for each split from all trees.

**Returns**

• feature_importances (array of shape [n_features] except for multi-class)

• linear model, which returns an array with shape (n_features, n_classes)

**property feature_names_in:** ndarray

Names of features seen during fit(). Defined only when X has feature names that are all strings.
**fit**(*X*, *y*, *, sample_weight=None, base_margin=None, eval_set=None, verbose=True, xgb_model=None, sample_weight_eval_set=None, base_margin_eval_set=None, feature_weights=None)

Fit gradient boosting classifier.

Note that calling fit() multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass xgb_model argument.

**Parameters**

- **X** (*Any*) – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.

  When the tree_method is set to hist, internally, the QuantileDMatrix will be used instead of the DMatrix for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a numpy array on CPU but cuda is used for training, then the data is first processed on CPU then transferred to GPU.

- **y** (*Any*) – Labels

- **sample_weight** (*Any | None*) – instance weights

- **base_margin** (*Any | None*) – Global bias for each instance. See Intercept for details.

- **eval_set** (*Sequence[Tuple[Any, Any]] | None*) – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.

- **verbose** (*bool | int | None*) – If verbose is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If verbose is an integer, the evaluation metric is printed at each verbose boosting stage. The last boosting stage / the boosting stage found by using early_stopping_rounds is also printed.

- **xgb_model** (*Booster | str | XGBModel | None*) – file name of stored XGBoost model or ‘Booster’ instance XGBoost model to be loaded before training (allows training continuation).

- **sample_weight_eval_set** (*Sequence[Any] | None*) – A list of the form [L_1, L_2, …, L_n], where each L_i is an array like object storing instance weights for the i-th validation set.

- **base_margin_eval_set** (*Sequence[Any] | None*) – A list of the form [M_1, M_2, …, M_n], where each M_i is an array like object storing base margin for the i-th validation set.

- **feature_weights** (*Any | None*) – Weight for each feature, defines the probability of each feature being selected when colsample is being used. All values must be greater than 0, otherwise a ValueError is thrown.

**Return type**

XGBClassifier

**get_booster()**

Get the underlying xgboost Booster of this model.

This will raise an exception when fit was not called

**Returns**

booster
Return type
a xgboost booster of underlying model

get_metadata_routing()
Get metadata routing of this object.

Please check User Guide on how the routing mechanism works.

Returns
routing – A MetadataRequest encapsulating routing information.

Return type
MetadataRequest

get_num_boosting_rounds()
Gets the number of xgboost boosting rounds.

Return type
int

get_params(deep=True)
Get parameters.

Parameters
deep (bool)

Return type
Dict[str, Any]

get_xgb_params()
Get xgboost specific parameters.

Return type
Dict[str, Any]

property intercept_: ndarray
Intercept (bias) property

For tree-based model, the returned value is the base_score.

Returns
intercept_

Return type
array of shape (1,) or [n_classes]

load_model(fname)
Load the model from a file or a bytearray.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

```python
model.load_model("model.json")
# or
model.load_model("model.ubj")
```

Parameters
fname (str | bytearray | PathLike) – Input file name or memory buffer(see also save_raw)
property n_features_in_: int
Number of features seen during fit().

predict(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)
Predict with X. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.

Parameters
• X (Any) – Data to predict with.
• output_margin (bool) – Whether to output the raw untransformed margin value.
• validate_features (bool) – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
• base_margin (Any | None) – Global bias for each instance. See Intercept for details.
• iteration_range (Tuple[int | integer, int | integer] | None) – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying iteration_range=([10, 20), then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

Added in version 1.4.0.

Return type
prediction

predict_proba(X, validate_features=True, base_margin=None, iteration_range=None)
Predict the probability of each X example being of a given class. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.

Parameters
• X (Any) – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.
• validate_features (bool) – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
• base_margin (Any | None) – Global bias for each instance. See Intercept for details.
• **iteration_range** *(Tuple[int | integer, int | integer] | None)* – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying *iteration_range=(10, 20)*, then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

**Returns**
a numpy array of shape array-like of shape (n_samples, n_classes) with the probability of each data example being of a given class.

**Return type**
prediction

**save_model**(fname)
Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

```python
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

**Parameters**

- **fname**(str | PathLike) – Output file name

**Return type**
None

**score**(X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X**(array-like of shape (n_samples, n_features)) – Test samples.
- **y**(array-like of shape (n_samples,) or (n_samples, n_outputs)) – True labels for X.
- **sample_weight**(array-like of shape (n_samples,), default=None) – Sample weights.

**Returns**

- **score** – Mean accuracy of self.predict(X) w.r.t. y.

**Return type**
float

**set_fit_request**(*, base_margin='UNCHANGED', base_margin_eval_set='UNCHANGED', eval_set='UNCHANGED', feature_weights='UNCHANGED', sample_weight='UNCHANGED', sample_weight_eval_set='UNCHANGED', verbose='UNCHANGED', xgb_model='UNCHANGED')
Request metadata passed to the fit method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.
The options for each parameter are:

- **True**: metadata is requested, and passed to `fit` if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to `fit`.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (`sklearn.utils.metadata_routing.UNCHANGED`) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
</table>

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a `Pipeline`. Otherwise it has no effect.

**Parameters**

- **base_margin**
  
  (str, True, False, or None, default=`sklearn.utils.metadata_routing.UNCHANGED`) – Metadata routing for `base_margin` parameter in `fit`.

- **base_margin_eval_set**
  
  (str, True, False, or None, default=`sklearn.utils.metadata_routing.UNCHANGED`) – Metadata routing for `base_margin_eval_set` parameter in `fit`.

- **eval_set**
  
  (str, True, False, or None, default=`sklearn.utils.metadata_routing.UNCHANGED`) – Metadata routing for `eval_set` parameter in `fit`.

- **feature_weights**
  
  (str, True, False, or None, default=`sklearn.utils.metadata_routing.UNCHANGED`) – Metadata routing for `feature_weights` parameter in `fit`.

- **sample_weight**
  
  (str, True, False, or None, default=`sklearn.utils.metadata_routing.UNCHANGED`) – Metadata routing for `sample_weight` parameter in `fit`.

- **sample_weight_eval_set**
  
  (str, True, False, or None, default=`sklearn.utils.metadata_routing.UNCHANGED`) – Metadata routing for `sample_weight_eval_set` parameter in `fit`.

- **verbose**
  
  (str, True, False, or None, default=`sklearn.utils.metadata_routing.UNCHANGED`) – Metadata routing for `verbose` parameter in `fit`.

- **xgb_model**
  
  (str, True, False, or None, default=`sklearn.utils.metadata_routing.UNCHANGED`) – Metadata routing for `xgb_model` parameter in `fit`.

- **self**

  (XGBClassifier)

**Returns**

- **self** – The updated object.
Return type
object

set_params(**params)
Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

Return type
self

Parameters
params (Any)

set_predict_proba_request(*, base_margin=sklearn.utils.metadata_routing.UNCHANGED, iteration_range=sklearn.utils.metadata_routing.UNCHANGED, validate_features=sklearn.utils.metadata_routing.UNCHANGED)

Request metadata passed to the predict_proba method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• True: metadata is requested, and passed to predict_proba if provided. The request is ignored if metadata is not provided.
• False: metadata is not requested and the meta-estimator will not pass it to predict_proba.
• None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
• str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

Note
This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

• base_margin (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict_proba.
• iteration_range (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict_proba.
• validate_features (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict_proba.
• self(XGBClassifier)
Returns

```
self -- The updated object.
```

Return type

```
object
```

```
set_predict_request(*, base_margin='UNCHANGED', iteration_range='UNCHANGED', output_margin='UNCHANGED', validate_features='UNCHANGED')
```

Request metadata passed to the `predict` method.

Note that this method is only relevant if `enable_metadata_routing=True` (see `sklearn.set_config()`). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to `predict` if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to `predict`.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (`sklearn.utils.metadata_routing.UNCHANGED`) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

### Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a `Pipeline`. Otherwise it has no effect.

**Parameters**

- **base_margin**

  (str, `True`, `False`, or `None`, default=`sklearn.utils.metadata_routing.UNCHANGED`) -- Metadata routing for `base_margin` parameter in `predict`.

- **iteration_range**

  (str, `True`, `False`, or `None`, default=`sklearn.utils.metadata_routing.UNCHANGED`) -- Metadata routing for `iteration_range` parameter in `predict`.

- **output_margin**

  (str, `True`, `False`, or `None`, default=`sklearn.utils.metadata_routing.UNCHANGED`) -- Metadata routing for `output_margin` parameter in `predict`.

- **validate_features**

  (str, `True`, `False`, or `None`, default=`sklearn.utils.metadata_routing.UNCHANGED`) -- Metadata routing for `validate_features` parameter in `predict`.

- **self** (`XGBClassifier`)

```
Returns

self -- The updated object.
```

Return type

```
object
```
**set_score_request(***, sample_weight={'UNCHANGED'})

Request metadata passed to the **score** method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.
set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to **score** if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to **score**.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a **Pipeline**. Otherwise it has no effect.

**Parameters**

- **sample_weight** *(str, True, False, or None, default=sklearn.utils.
metadata_routing.UNCHANGED)* – Metadata routing for sample_weight parameter in score.

- **self** *(XGBClassifier)*

**Returns**

self – The updated object.

**Return type**

object

class xgboost.XGBRanker(***, objective='rank:ndcg', **kwargs)

**Parameters**

- **n_estimators** *(Optional[int])* – Number of gradient boosted trees. Equivalent to number of boosting rounds.

- **max_depth** *(Optional[int])* – Maximum tree depth for base learners.

- **max_leaves** *(Optional[int])* – Maximum number of leaves; 0 indicates no limit.

- **max_bin** *(Optional[int])* – If using histogram-based algorithm, maximum number of bins per feature
• **grow_policy** *(Optional[|str|])* – Tree growing policy.
  - deepwise: Favors splitting at nodes closest to the node,
  - lossguide: Favors splitting at nodes with highest loss change.

• **learning_rate** *(Optional[float]*) – Boosting learning rate (xgb’s “eta”)

• **verbosity** *(Optional[int]*) – The degree of verbosity. Valid values are 0 (silent) - 3 (debug).

• **objective** *(Union[|str|, xgboost.sklearn._SklObjWProto, Callable[[|Any, Any|], Tuple[numpy.ndarray, numpy.ndarray]], NoneType]*) – Specify the learning task and the corresponding learning objective or a custom objective function to be used.
  For custom objective, see **Custom Objective and Evaluation Metric** and **Custom objective and metric** for more information, along with the end note for function signatures.

• **booster** *(Optional[|str|])* – Specify which booster to use: gbtree, gblinear or dart.

• **tree_method** *(Optional[|str|])* – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available.
  It’s recommended to study this option from the parameters document **tree method**

• **n_jobs** *(Optional[int]*) – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.

• **gamma** *(Optional[float]*) – (min_split_loss) Minimum loss reduction required to make a further partition on a leaf node of the tree.

• **min_child_weight** *(Optional[float]*) – Minimum sum of instance weight(hessian) needed in a child.

• **max_delta_step** *(Optional[float]*) – Maximum delta step we allow each tree’s weight estimation to be.

• **subsample** *(Optional[float]*) – Subsample ratio of the training instance.

• **sampling_method** *(Optional[|str|])* – Sampling method. Used only by the GPU version of hist tree method.
  - uniform: Select random training instances uniformly.
  - gradient_based: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)

• **colsample_bytree** *(Optional[float]*) – Subsample ratio of columns when constructing each tree.

• **colsample_bylevel** *(Optional[float]*) – Subsample ratio of columns for each level.

• **colsample_bynode** *(Optional[float]*) – Subsample ratio of columns for each split.

• **reg_alpha** *(Optional[float]*) – L1 regularization term on weights (xgb’s alpha).

• **reg_lambda** *(Optional[float]*) – L2 regularization term on weights (xgb’s lambda).

• **scale_pos_weight** *(Optional[float]*) – Balancing of positive and negative weights.

• **base_score** *(Optional[float]*) – The initial prediction score of all instances, global bias.
• random_state (Union[numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType]) – Random number seed.

**Note**
Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.

• missing (float) – Value in the data which needs to be present as a missing value. Default to numpy.nan.

• num_parallel_tree (Optional[int]) – Used for boosting random forest.

• monotone_constraints (Union[Dict[str, int], str, NoneType]) – Constraint of variable monotonicity. See tutorial for more information.

• interaction_constraints (Union[str, List[Tuple[str]], NoneType]) – Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nested list, e.g. [[[0, 1], [2, 3, 4]], where each inner list is a group of indices of features that are allowed to interact with each other. See tutorial for more information.

• importance_type (Optional[str]) – The feature importance type for the feature_importances_ property:
  – For tree model, it’s either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  – For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

• device (Optional[str]) – Added in version 2.0.0.
  Device ordinal, available options are cpu, cuda, and gpu.

• validate_parameters (Optional[bool]) – Give warnings for unknown parameter.

• enable_categorical (bool) – See the same parameter of DMatrix for details.

• feature_types (Optional[Sequence[str]]) – Added in version 1.7.0.
  Used for specifying feature types without constructing a dataframe. See DMatrix for details.

• max_cat_to_onehot (Optional[int]) – Added in version 1.6.0.

**Note**
This parameter is experimental

A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, enable_categorical needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

• max_cat_threshold (Optional[int]) – Added in version 1.7.0.
**Note**

This parameter is experimental

Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, `enable_categorical` needs to be set to have categorical feature support. See *Categorical Data* and *Parameters for Categorical Feature* for details.

- **multi_strategy** *(Optional [str]*) – Added in version 2.0.0.

**Note**

This parameter is working-in-progress.

The strategy used for training multi-target models, including multi-target regression and multi-class classification. See *Multiple Outputs* for more information.

- one_output_per_tree: One model for each target.
- multi_output_tree: Use multi-target trees.

- **eval_metric** *(Union [str, List [str], Callable, NoneType]*) – Added in version 1.6.0.

  Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in sklearn.metrics, or any other user defined metric that looks like sklearn.metrics.

  If custom objective is also provided, then custom metric should implement the corresponding reverse link function.

  Unlike the `scoring` parameter commonly used in scikit-learn, when a callable object is provided, it’s assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

  For advanced usage on Early stopping like directly choosing to maximize instead of minimize, see `xgboost.callback.EarlyStopping`.

  See *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information.

```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

- **early_stopping_rounds** *(Optional [int]*) – Added in version 1.6.0.

  - Activates early stopping. Validation metric needs to improve at least once in every `early_stopping_rounds` round(s) to continue training. Requires at least one item in `eval_set` in `fit()`.
- If early stopping occurs, the model will have two additional attributes: `best_score` and `best_iteration`. These are used by the `predict()` and `apply()` methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the `iteration_range` in these inference methods. In addition, other utilities like model plotting can also use the entire model.

- If you prefer to discard the trees after `best_iteration`, consider using the callback function `xgboost.callback.EarlyStopping`.

- If there’s more than one item in `eval_set`, the last entry will be used for early stopping. If there’s more than one metric in `eval_metric`, the last metric will be used for early stopping.

- **callbacks** (*Optional* [*List* [*xgboost.callback.TrainingCallback*]]) – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using `Callback API`.

```
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    reg = xgboost.XGBRegressor(**params, callbacks=callbacks)
    reg.fit(X, y)
```

- **kwargs** (*Optional* [*Any]*) – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found *here*. Attempting to set a parameter via the constructor args and **kwargs dict simultaneously will result in a TypeError.

```
**kwargs unsupported by scikit-learn
**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed
via this argument will interact properly with scikit-learn.
```

```
Note

A custom objective function is currently not supported by XGBRanker.
```

```
Note

Query group information is only required for ranking training but not prediction. Multiple
groups can be predicted on a single call to `predict()`.
```

When fitting the model with the `group` parameter, your data need to be sorted by the query
group first. `group` is an array that contains the size of each query group.
Similarly, when fitting the model with the \textit{qid} parameter, the data should be sorted according to query index and \textit{qid} is an array that contains the query index for each training sample.

For example, if your original data look like:

\begin{verbatim}
  qid  label  features
  1    0      x_1
  1    1      x_2
  1    0      x_3
  2    0      x_4
  2    1      x_5
  2    1      x_6
  2    1      x_7
\end{verbatim}

then \textit{fit()} method can be called with either \textit{group} array as [3, 4] or with \textit{qid} as [1, 1, 1, 2, 2, 2, 2], that is the qid column. Also, the \textit{qid} can be a special column of input $X$ instead of a separated parameter, see \textit{fit()} for more info.

\textbf{apply}(X, iteration_range=None)

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then \textit{best_iteration} is used automatically.

Parameters

- $X$ (array_like, shape=[n_samples, n_features]) – Input features matrix.
- iteration_range (Tuple[int | integer, int | integer] | None) – See predict().

Returns

$X$ \_leaves – For each datapoint $x$ in $X$ and for each tree, return the index of the leaf $x$ ends up in. Leaves are numbered within $[0; 2^{\text{self.max_depth}+1})$, possibly with gaps in the numbering.

Return type

array_like, shape=[n_samples, n_trees]

property best_iteration: int

The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is the first round, then best_iteration is 0.

property best_score: float

The best score obtained by early stopping.

property coef_: ndarray

Coefficients property

\begin{itemize}
  \item \textbf{Note}
  
  Coefficients are defined only for linear learners
  
  Coefficients are only defined when the linear model is chosen as base learner (booster=gblinear). It is not defined for other base learner types, such as tree learners (booster=gbtree).
\end{itemize}

Returns

c coef_
Return type
array of shape [n_features] or [n_classes, n_features]

evals_result()
Return the evaluation results.
If eval_set is passed to the fit() function, you can call evals_result() to get evaluation results for all passed eval_sets. When eval_metric is also passed to the fit() function, the evals_result will contain the eval_metrics passed to the fit() function.

The returned evaluation result is a dictionary:

```
{ 'validation_0': { 'logloss': [ '0.604835', '0.531479']},
 'validation_1': { 'logloss': [ '0.419650', '0.176860']}}
```

property feature_importances_: ndarray
Feature importances property, return depends on importance_type parameter. When model trained with multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “average” is defined based on the importance type. For instance, if the importance type is “total_gain”, then the score is sum of loss change for each split from all trees.

Returns
- feature_importances_ (array of shape [n_features] except for multi-class)
- linear model, which returns an array with shape (n_features, n_classes)

property feature_names_in_: ndarray
Names of features seen during fit(). Defined only when X has feature names that are all strings.

fit(X, y, *, group=None, qid=None, sample_weight=None, base_margin=None, eval_set=None, eval_group=None, eval_qid=None, verbose=False, xgb_model=None, sample_weight_eval_set=None, base_margin_eval_set=None, feature_weights=None)
Fit gradient boosting ranker

Note that calling fit() multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass xgb_model argument.

Parameters
- X (Any) – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.

When this is a pandas.DataFrame or a cudf.DataFrame, it may contain a special column called qid for specifying the query index. Using a special column is the same as using the qid parameter, except for being compatible with sklearn utility functions like sklearn.model_selection.cross_validation(). The same convention applies to the XGBRanker.score() and XGBRanker.predict().

<table>
<thead>
<tr>
<th>qid</th>
<th>feat_0</th>
<th>feat_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>x_{00}</td>
<td>x_{01}</td>
</tr>
<tr>
<td>1</td>
<td>x_{10}</td>
<td>x_{11}</td>
</tr>
<tr>
<td>1</td>
<td>x_{20}</td>
<td>x_{21}</td>
</tr>
</tbody>
</table>
When the tree_method is set to hist, internally, the QuantileDMatrix will be used instead of the DMatrix for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a numpy array on CPU but cuda is used for training, then the data is first processed on CPU then transferred to GPU.

- **y** (*Any*) – Labels
- **group** (*Any* | *None*) – Size of each query group of training data. Should have as many elements as the query groups in the training data. If this is set to None, then user must provide qid.
- **qid** (*Any* | *None*) – Query ID for each training sample. Should have the size of n_samples. If this is set to None, then user must provide group or a special column in X.
- **sample_weight** (*Any* | *None*) – Query group weights

### Note
Weights are per-group for ranking tasks

In ranking task, one weight is assigned to each query group/id (not each data point). This is because we only care about the relative ordering of data points within each group, so it doesn’t make sense to assign weights to individual data points.

- **base_margin** (*Any* | *None*) – Global bias for each instance. See Intercept for details.
- **eval_set** (*Sequence*[Tuple[*Any*, *Any*]]* | *None*) – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.
- **eval_group** (*Sequence[*Any*] | *None*) – A list in which eval_group[i] is the list containing the sizes of all query groups in the i-th pair in eval_set.
- **eval_qid** (*Sequence[*Any*] | *None*) – A list in which eval_qid[i] is the array containing query ID of i-th pair in eval_set. The special column convention in X applies to validation datasets as well.
- **verbose** (*bool* | *int* | *None*) – If verbose is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If verbose is an integer, the evaluation metric is printed at each verbose boosting stage. The last boosting stage / the boosting stage found by using early_stopping_rounds is also printed.
- **xgb_model** (*Booster* | *str* | *XGBModel* | *None*) – file name of stored XGBoost model or ‘Booster’ instance XGBoost model to be loaded before training (allows training continuation).
- **sample_weight_eval_set** (*Sequence[*Any*] | *None*) – A list of the form [L_1, L_2, …, L_n], where each L_i is a list of group weights on the i-th validation set.
it doesn’t make sense to assign weights to individual data points.

- **base_margin_eval_set** *(Sequence[Any] | None)* – A list of the form \([M_1, M_2, \ldots, M_n]\), where each \(M_i\) is an array like object storing base margin for the \(i\)-th validation set.

- **feature_weights** *(Any | None)* – Weight for each feature, defines the probability of each feature being selected when colsample is being used. All values must be greater than 0, otherwise a `ValueError` is thrown.

**Return type**
XGBRanker

**get_booster()**
Get the underlying xgboost Booster of this model.

This will raise an exception when fit was not called

**Returns**
booster

**Return type**
a xgboost booster of underlying model

**get_metadata_routing()**
Get metadata routing of this object.

Please check User Guide on how the routing mechanism works.

**Returns**
routing – A `MetadataRequest` encapsulating routing information.

**Return type**
`MetadataRequest`

**get_num_boosting_rounds()**
Gets the number of xgboost boosting rounds.

**Return type**
`int`

**get_params**(deep=True)
Get parameters.

**Parameters**
depth (bool)

**Return type**
`Dict[str, Any]`

**get_xgb_params()**
Get xgboost specific parameters.

**Return type**
`Dict[str, Any]`

**property intercept_**: `ndarray`
Intercept (bias) property

For tree-based model, the returned value is the `base_score`. 
Returns

*intercept_*

Return type

array of shape (1,) or [n_classes]

**load_model**(fname)

Load the model from a file or a bytearray.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

```python
model.load_model("model.json")
# or
model.load_model("model.ubj")
```

**Parameters**

- **fname** (str | bytearray | PathLike) – Input file name or memory buffer(see also save_raw)

**Return type**

None

**property n_features_in_**: int

Number of features seen during fit().

**predict**(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)

Predict with X. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.

**Note**

This function is only thread safe for gbtree and dart.

**Parameters**

- **X** (Any) – Data to predict with.
- **output_margin** (bool) – Whether to output the raw untransformed margin value.
- **validate_features** (bool) – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
- **base_margin** (Any | None) – Global bias for each instance. See Intercept for details.
- **iteration_range** (Tuple[int | integer, int | integer] | None) – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying iteration_range=(10, 20), then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

Added in version 1.4.0.

**Return type**

prediction
**save_model**(fname)

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See *Model IO* for more info.

```python
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

**Parameters**

**fname** *(str | PathLike)* – Output file name

**Return type**

None

**score**(X, y)

Evaluate score for data using the last evaluation metric. If the model is trained with early stopping, then *best_iteration* is used automatically.

**Parameters**

- **X** *(Union[pd.DataFrame, cudf.DataFrame])* – Feature matrix. A DataFrame with a special *qid* column.
- **y** *(Any)* – Labels

**Returns**

The result of the first evaluation metric for the ranker.

**Return type**

score

**set_fit_request**(*, base_margin='UNCHANGED', base_margin_eval_set='UNCHANGED',
eval_group='UNCHANGED', eval_qid='UNCHANGED',
eval_set='UNCHANGED', feature_weights='UNCHANGED',
group='UNCHANGED', qid='UNCHANGED', sample_weight='UNCHANGED',
sample_weight_eval_set='UNCHANGED', verbose='UNCHANGED',
xgb_model='UNCHANGED')

Request metadata passed to the *fit* method.

Note that this method is only relevant if *enable_metadata_routing=True* (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to *fit* if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to *fit*.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.
Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

- **base_margin**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in fit.

- **base_margin_eval_set**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin_eval_set parameter in fit.

- **eval_group**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for eval_group parameter in fit.

- **eval_qid**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for eval_qid parameter in fit.

- **eval_set**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for eval_set parameter in fit.

- **feature_weights**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for feature_weights parameter in fit.

- **group**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for group parameter in fit.

- **qid**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for qid parameter in fit.

- **sample_weight**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight parameter in fit.

- **sample_weight_eval_set**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight_eval_set parameter in fit.

- **verbose**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for verbose parameter in fit.

- **xgb_model**  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for xgb_model parameter in fit.

- **self** (XGBRanker)

Returns

self – The updated object.

Return type

object
**set_params(**params)

Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

**Return type**

self

**Parameters**

params (Any)

**set_predict_request(***, base_margin='UNCHANGED', iteration_range='UNCHANGED', output_margin='UNCHANGED', validate_features='UNCHANGED')

Request metadata passed to the predict method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to predict if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to predict.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

**Parameters**

- **base_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict.
- **iteration_range** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict.
- **output_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for output_margin parameter in predict.
- **validate_features** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict.
- **self** (XGBRanker)
Returns
self – The updated object.

Return type
object
class xgboost.XGBRFRegressor(*, learning_rate=1.0, subsample=0.8, colsample_bynode=0.8, reg_lambda=1e-05, **kwargs)

Bases: XGBRegressor
scikit-learn API for XGBoost random forest regression. See Using the Scikit-Learn Estimator Interface for more information.

Parameters

• n_estimators (Optional [int]) – Number of trees in random forest to fit.
• max_depth (Optional [int]) – Maximum tree depth for base learners.
• max_leaves (Optional [int]) – Maximum number of leaves; 0 indicates no limit.
• max_bin (Optional [int]) – If using histogram-based algorithm, maximum number of bins per feature
• grow_policy (Optional [str]) – Tree growing policy.
  – depthwise: Favors splitting at nodes closest to the root,
  – lossguide: Favors splitting at nodes with highest loss change.
• learning_rate (Optional [float]) – Boosting learning rate (xgb’s “eta”)  
• verbosity (Optional [int]) – The degree of verbosity. Valid values are 0 (silent) - 3 (debug).
• objective (Union [str, xgboost.sklearn._Sk1ObjWProto, Callable[[Any, Any], Tuple[numpy.ndarray, numpy.ndarray]], NoneType]) – Specify the learning task and the corresponding learning objective or a custom objective function to be used.

For custom objective, see Custom Objective and Evaluation Metric and Custom objective and metric for more information, along with the end note for function signatures.
• booster (Optional [str]) – Specify which booster to use: gbtree, gblinear or dart.
• tree_method (Optional [str]) – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available. It’s recommended to study this option from the parameters document tree method
• n_jobs (Optional [int]) – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.
• gamma (Optional [float]) – (min_split_loss) Minimum loss reduction required to make a further partition on a leaf node of the tree.
• min_child_weight (Optional [float]) – Minimum sum of instance weight(hessian) needed in a child.
• max_delta_step (Optional [float]) – Maximum delta step we allow each tree’s weight estimation to be.
• subsample (Optional [float]) – Subsample ratio of the training instance.
• **sampling_method** (*Optional*[str]) – Sampling method. Used only by the GPU version of hist tree method.
  - uniform: Select random training instances uniformly.
  - gradient_based: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)

• **colsample_bytree** (*Optional*[float]) – Subsample ratio of columns when constructing each tree.

• **colsample_bylevel** (*Optional*[float]) – Subsample ratio of columns for each level.

• **colsample_bynode** (*Optional*[float]) – Subsample ratio of columns for each split.

• **reg_alpha** (*Optional*[float]) – L1 regularization term on weights (xgb’s alpha).

• **reg_lambda** (*Optional*[float]) – L2 regularization term on weights (xgb’s lambda).

• **scale_pos_weight** (*Optional*[float]) – Balancing of positive and negative weights.

• **base_score** (*Optional*[float]) – The initial prediction score of all instances, global bias.

• **random_state** (*Union*[numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType]*) – Random number seed.

### Note

Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.

• **missing** (float) – Value in the data which needs to be present as a missing value. Default to numpy.nan.

• **num_parallel_tree** (*Optional*[int]) – Used for boosting random forest.

• **monotone_constraints** (*Union*[Dict[str, int], str, NoneType]*) – Constraint of variable monotonicity. See tutorial for more information.

• **interaction_constraints** (*Union*[str, List[Tuple[str]], NoneType]*) – Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nested list, e.g. [[0, 1], [2, 3, 4]], where each inner list is a group of indices of features that are allowed to interact with each other. See tutorial for more information.

• **importance_type** (*Optional*[str]) – The feature importance type for the feature_importances_ property:
  - For tree model, it's either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  - For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

• **device** (*Optional*[str]) – Added in version 2.0.0.

  Device ordinal, available options are cpu, cuda, and gpu.

• **validate_parameters** (*Optional*[bool]) – Give warnings for unknown parameter.

• **enable_categorical** (bool) – See the same parameter of DMatrix for details.

• **feature_types** (*Optional*[Sequence[str]]) – Added in version 1.7.0.

  Used for specifying feature types without constructing a dataframe. See DMatrix for details.
• **max_cat_to_onehot** *(Optional[int]*) – Added in version 1.6.0.

  A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, `enable_categorical` needs to be set to have categorical feature support. See *Categorical Data* and *Parameters for Categorical Feature* for details.

• **max_cat_threshold** *(Optional[int]*) – Added in version 1.7.0.

  Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, `enable_categorical` needs to be set to have categorical feature support. See *Categorical Data* and *Parameters for Categorical Feature* for details.

• **multi_strategy** *(Optional[str]*) – Added in version 2.0.0.

  The strategy used for training multi-target models, including multi-target regression and multi-class classification. See *Multiple Outputs* for more information.

  - `one_output_per_tree`: One model for each target.
  - `multi_output_tree`: Use multi-target trees.

• **eval_metric** *(Union[str, List[str], Callable, NoneType]*) – Added in version 1.6.0.

  Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in `sklearn.metrics`, or any other user defined metric that looks like `sklearn.metrics`.

  If custom objective is also provided, then custom metric should implement the corresponding reverse link function.

  Unlike the `scoring` parameter commonly used in scikit-learn, when a callable object is provided, it’s assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

  For advanced usage on Early stopping like directly choosing to maximize instead of minimize, see `xgboost.callback.EarlyStopping`.

  See *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information.
```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

- **early_stopping_rounds** (*Optional*[int]) – Added in version 1.6.0.
  - Activates early stopping. Validation metric needs to improve at least once in every `early_stopping_rounds` round(s) to continue training. Requires at least one item in `eval_set` in `fit()`.
  - If early stopping occurs, the model will have two additional attributes: `best_score` and `best_iteration`. These are used by the `predict()` and `apply()` methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the `iteration_range` in these inference methods. In addition, other utilities like model plotting can also use the entire model.
  - If you prefer to discard the trees after `best_iteration`, consider using the callback function `xgboost.callback.EarlyStopping`.
  - If there’s more than one item in `eval_set`, the last entry will be used for early stopping. If there’s more than one metric in `eval_metric`, the last metric will be used for early stopping.

- **callbacks** (*Optional*[List[`xgboost.callback.TrainingCallback]]) – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using `Callback API`.

```python
Note
States in callback are not preserved during training, which means callback objects cannot be reused for multiple training sessions without reinitialization or deepcopy.
```

```python
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    reg = xgboost.XGBRegressor(**params, callbacks=callbacks)
    reg.fit(X, y)
```

- **kwargs** (*Optional*[Any]) – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found `here`. Attempting to set a parameter via the constructor args and **kwargs dict simultaneously will result in a TypeError.

```python
Note
**kwargs unsupported by scikit-learn
**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed via this argument will interact properly with scikit-learn.
```
**Note**

Custom objective function

A custom objective function can be provided for the `objective` parameter. In this case, it should have the signature `objective(y_true, y_pred) -> [grad, hess]` or `objective(y_true, y_pred, *, sample_weight) -> [grad, hess]`:

- **y_true**: array_like of shape [n_samples]
  - The target values
- **y_pred**: array_like of shape [n_samples]
  - The predicted values
- **sample_weight**: Optional sample weights.
- **grad**: array_like of shape [n_samples]
  - The value of the gradient for each sample point.
- **hess**: array_like of shape [n_samples]
  - The value of the second derivative for each sample point

```python
apply(X, iteration_range=None)
```

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then `best_iteration` is used automatically.

**Parameters**

- **X** (array_like, shape=[n_samples, n_features]) – Input features matrix.
- **iteration_range** (Tuple[int | integer, int | integer] | None) – See `predict()`.

**Returns**

- **X_leaves** – For each datapoint x in X and for each tree, return the index of the leaf x ends up in. Leaves are numbered within `[0; 2**(self.max_depth+1))`, possibly with gaps in the numbering.

**Return type**

array_like, shape=[n_samples, n_trees]

**property best_iteration**: int

The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is the first round, then `best_iteration` is 0.

**property best_score**: float

The best score obtained by early stopping.

**property coef_**: ndarray

Coefficients property

**Note**

Coefficients are defined only for linear learners

Coefficients are only defined when the linear model is chosen as base learner (`booster=gblinear`). It is not defined for other base learner types, such as tree learners (`booster=gbtree`).
Returns

coef_

Return type

array of shape \([n\_features]\) or \([n\_classes, n\_features]\)

evals_result()

Return the evaluation results.

If eval_set is passed to the fit() function, you can call evals_result() to get evaluation results for all passed eval_sets. When eval_metric is also passed to the fit() function, the evals_result will contain the eval_metrics passed to the fit() function.

The returned evaluation result is a dictionary:

```python
{'validation_0': {'logloss': ['0.604835', '0.531479']},
 'validation_1': {'logloss': ['0.41965', '0.17686']}}
```

Return type

evals_result

property feature_importances_: ndarray

Feature importances property, return depends on importance_type parameter. When model trained with multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “average” is defined based on the importance type. For instance, if the importance type is “total_gain”, then the score is sum of loss change for each split from all trees.

Returns

• feature_importances_ (array of shape \([n\_features]\) except for multi-class)
• linear model, which returns an array with shape \((n\_features, n\_classes)\)

property feature_names_in_: ndarray

Names of features seen during fit(). Defined only when X has feature names that are all strings.

```
fit(X, y, *, sample_weight=None, base_margin=None, eval_set=None, verbose=True, xgb_model=None, sample_weight_eval_set=None, base_margin_eval_set=None, feature_weights=None)
```

Fit gradient boosting model.

Note that calling fit() multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass xgb_model argument.

Parameters

• X (Any) – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.

  When the tree_method is set to hist, internally, the QuantileDMatrix will be used instead of the DMatrix for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a numpy array on CPU but cuda is used for training, then the data is first processed on CPU then transferred to GPU.

• y (Any) – Labels

• sample_weight (Any | None) – instance weights

• base_margin (Any | None) – Global bias for each instance. See Intercept for details.
• **eval_set** (*Sequence[(Any, Any)] | None*) – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.

• **verbose** (*bool | int | None*) – If *verbose* is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If *verbose* is an integer, the evaluation metric is printed at each *verbose* boosting stage. The last boosting stage / the boosting stage found by using *early_stopping_rounds* is also printed.

• **xgb_model** (*Booster | str | XGBModel | None*) – file name of stored XGBoost model or `Booster` instance XGBoost model to be loaded before training (allows training continuation).

• **sample_weight_eval_set** (*Sequence[Any] | None*) – A list of the form \([L_1, L_2, \ldots, L_n]\), where each \(L_i\) is an array like object storing instance weights for the i-th validation set.

• **base_margin_eval_set** (*Sequence[Any] | None*) – A list of the form \([M_1, M_2, \ldots, M_n]\), where each \(M_i\) is an array like object storing base margin for the i-th validation set.

• **feature_weights** (*Any | None*) – Weight for each feature, defines the probability of each feature being selected when colsample is being used. All values must be greater than 0, otherwise a `ValueError` is thrown.

**Return type**

`XGBRFRegressor`

get_booster()

Get the underlying xgboost Booster of this model.

This will raise an exception when fit was not called

Returns

booster

Return type

a xgboost booster of underlying model

get_metadata_routing()

Get metadata routing of this object.

Please check User Guide on how the routing mechanism works.

Returns

routing – A `MetadataRequest` encapsulating routing information.

Return type

`MetadataRequest`

get_num_boosting_rounds()

Gets the number of xgboost boosting rounds.

Return type

int

get_params(*deep=True*)

Get parameters.

Parameters

*deep* (*bool*)
Return type

\[ \text{Dict} [\text{str}, \text{Any}] \]

get_xgb_params()

Get xgboost specific parameters.

Return type

\[ \text{Dict} [\text{str}, \text{Any}] \]

property intercept_:

ndarray

Intercept (bias) property

For tree-based model, the returned value is the base_score.

Returns

intercept_

Return type

array of shape (1,) or [n_classes]

load_model(fname)

Load the model from a file or a bytarray.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

```python
model.load_model("model.json")
# or
model.load_model("model.ubj")
```

Parameters

- **fname** (str | bytearray | PathLike) – Input file name or memory buffer (see also save_raw)

Return type

None

property n_features_in_:

int

Number of features seen during fit().

predict(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)

Predict with X. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.

Note

This function is only thread safe for gbtree and dart.

Parameters

- **X** (Any) – Data to predict with.
- **output_margin** (bool) – Whether to output the raw untransformed margin value.
- **validate_features** (bool) – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
• **base_margin** (*Any* | *None*) – Global bias for each instance. See *Intercept* for details.

• **iteration_range** (*Tuple[int | integer, int | integer]* | *None*) – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying **iteration_range**=(10, 20), then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

  Added in version 1.4.0.

**Return type**

prediction

### save_model (*fname*)

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See *Model IO* for more info.

```python
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

**Parameters**

- **fname** (*str* | *PathLike*) – Output file name

**Return type**

*None*

### score (*X*, *y*, *sample_weight=None*)

Return the coefficient of determination of the prediction.

The coefficient of determination $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).\text{sum}()$ and $v$ is the total sum of squares $((y_{true} - y_{true}.\text{mean}())^2).\text{sum}()$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

**Parameters**

- **X** (*array-like of shape (n_samples, n_features)*) – Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.

- **y** (*array-like of shape (n_samples,) or (n_samples, n_outputs]*) – True values for $X$.

- **sample_weight** (*array-like of shape (n_samples,)*, *default=None*) – Sample weights.

**Returns**

- **score** – $R^2$ of self.predict(X) w.r.t. $y$.

**Return type**

*float*
Notes

The $R^2$ score used when calling `score` on a regressor uses `multioutput='uniform_average'` from version 0.23 to keep consistent with default value of `r2_score()`. This influences the `score` method of all the multioutput regressors (except for `MultiOutputRegressor`).

```
set_fit_request(*, base_margin='UNCHANGED', base_margin_eval_set='UNCHANGED',
                eval_set='UNCHANGED', feature_weights='UNCHANGED',
                sample_weight='UNCHANGED', sample_weight_eval_set='UNCHANGED',
                verbose='UNCHANGED', xgb_model='UNCHANGED')
```

Request metadata passed to the `fit` method.

Note that this method is only relevant if `enable_metadata_routing=True` (see `sklearn.set_config()`). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to `fit` if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to `fit`.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a `Pipeline`. Otherwise it has no effect.

**Parameters**

- **base_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for `base_margin` parameter in `fit`.
- **base_margin_eval_set** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for `base_margin_eval_set` parameter in `fit`.
- **eval_set** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for `eval_set` parameter in `fit`.
- **feature_weights** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for `feature_weights` parameter in `fit`.
- **sample_weight** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for `sample_weight` parameter in `fit`. 
• **sample_weight_eval_set** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight_eval_set parameter in fit.

• **verbose** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for verbose parameter in fit.

• **xgb_model** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for xgb_model parameter in fit.

• self (XGBRFRegressor)

Returns

self – The updated object.

Return type

object

**set_params(****params**)

Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

Return type

self

Parameters

params *(Any)*

**set_predict_request** (*, base_margin='UNCHANGEDS', iteration_range='UNCHANGEDS', output_margin='UNCHANGEDS', validate_features='UNCHANGEDS')

Request metadata passed to the predict method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• **True**: metadata is requested, and passed to predict if provided. The request is ignored if metadata is not provided.

• **False**: metadata is not requested and the meta-estimator will not pass it to predict.

• **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.

• **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.
Parameters

- **base_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict.

- **iteration_range** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict.

- **output_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for output_margin parameter in predict.

- **validate_features** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict.

- **self** (XGBRFRegressor)

Returns

self – The updated object.

Return type

object

**set_score_request(***, sample_weight='UNCHANGEDS')***

Request metadata passed to the score method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- True: metadata is requested, and passed to score if provided. The request is ignored if metadata is not provided.
- False: metadata is not requested and the meta-estimator will not pass it to score.
- None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

- **sample_weight** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight parameter in score.

- **self** (XGBRFRegressor)
Returns

self – The updated object.

Return type

object

class xgboost.XGBRFClassifier(*, learning_rate=1.0, subsample=0.8, colsample_bynode=0.8, reg_lambda=1e-05, **kwargs)

Bases: XGBClassifier

scikit-learn API for XGBoost random forest classification. See Using the Scikit-Learn Estimator Interface for more information.

Parameters

- **n_estimators (Optional[int])** – Number of trees in random forest to fit.
- **max_depth (Optional[int])** – Maximum tree depth for base learners.
- **max_leaves (Optional[int])** – Maximum number of leaves; 0 indicates no limit.
- **max_bin (Optional[int])** – If using histogram-based algorithm, maximum number of bins per feature
- **grow_policy (Optional[str])** – Tree growing policy.
  - depthwise: Favors splitting at nodes closest to the node,
  - lossguide: Favors splitting at nodes with highest loss change.
- **learning_rate (Optional[float])** – Boosting learning rate (xgb’s “eta”)
- **verbosity (Optional[int])** – The degree of verbosity. Valid values are 0 (silent) - 3 (debug).
- **objective** (Union[str, xgboost.sklearn._SklObjWProto, Callable[[Any, Any], Tuple[numpy.ndarray, numpy.ndarray]], NoneType]) – Specify the learning task and the corresponding learning objective or a custom objective function to be used.
  For custom objective, see Custom Objective and Evaluation Metric and Custom objective and metric for more information, along with the end note for function signatures.
- **booster (Optional[str])** – Specify which booster to use: gbtree, gblinear or dart.
- **tree_method (Optional[str])** – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available. It’s recommended to study this option from the parameters document tree method
- **n_jobs (Optional[int])** – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.
- **gamma (Optional[float])** – (min_split_loss) Minimum loss reduction required to make a further partition on a leaf node of the tree.
- **min_child_weight (Optional[float])** – Minimum sum of instance weight(hessian) needed in a child.
- **max_delta_step (Optional[float])** – Maximum delta step we allow each tree’s weight estimation to be.
- **subsample (Optional[float])** – Subsample ratio of the training instance.
• 
• **sampling_method** *(Optional[str])* – Sampling method. Used only by the GPU version of hist tree method.
  
  – `uniform`: Select random training instances uniformly.
  
  – `gradient_based`: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)

• **colsample_bytree** *(Optional[float])* – Subsample ratio of columns when constructing each tree.

• **colsample_bylevel** *(Optional[float])* – Subsample ratio of columns for each level.

• **colsample_bynode** *(Optional[float])* – Subsample ratio of columns for each split.

• **reg_alpha** *(Optional[float])* – L1 regularization term on weights (xgb’s alpha).

• **reg_lambda** *(Optional[float])* – L2 regularization term on weights (xgb’s lambda).

• **scale_pos_weight** *(Optional[float])* – Balancing of positive and negative weights.

• **base_score** *(Optional[float])* – The initial prediction score of all instances, global bias.

• **random_state** *(Union[numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType])* – Random number seed.

---

**Note**

Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.

• **missing** *(float)* – Value in the data which needs to be present as a missing value. Default to `numpy.nan`.

• **num_parallel_tree** *(Optional[int])* – Used for boosting random forest.

• **monotone_constraints** *(Union[Dict[str, int], str, NoneType])* – Constraint of variable monotonicity. See tutorial for more information.

• **interaction_constraints** *(Union[str, List[Tuple[str]], NoneType])* – Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nested list, e.g. `[[0, 1], [2, 3, 4]]`, where each inner list is a group of indices of features that are allowed to interact with each other. See tutorial for more information

• **importance_type** *(Optional[str])* – The feature importance type for the feature_importances_ property:
  
  – For tree model, it’s either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  
  – For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

• **device** *(Optional[str])* – Added in version 2.0.0.
  
  Device ordinal, available options are `cpu`, `cuda`, and `gpu`.

• **validate_parameters** *(Optional[bool])* – Give warnings for unknown parameter.

• **enable_categorical** *(bool)* – See the same parameter of `DMatrix` for details.

• **feature_types** *(Optional[Sequence[str]])* – Added in version 1.7.0.
  
  Used for specifying feature types without constructing a dataframe. See `DMatrix` for details.
• **max_cat_to_onehot** *(Optional [int])* – Added in version 1.6.0.

  - **Note**
  
  This parameter is experimental

  A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, *enable_categorical* needs to be set to have categorical feature support. See *Categorical Data* and *Parameters for Categorical Feature* for details.

• **max_cat_threshold** *(Optional [int])* – Added in version 1.7.0.

  - **Note**
  
  Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, *enable_categorical* needs to be set to have categorical feature support. See *Categorical Data* and *Parameters for Categorical Feature* for details.

• **multi_strategy** *(Optional [str])* – Added in version 2.0.0.

  - **Note**
  
  This parameter is working-in-progress.

  The strategy used for training multi-target models, including multi-target regression and multi-class classification. See *Multiple Outputs* for more information.

  – one_output_per_tree: One model for each target.
  

• **eval_metric** *(Union [str, List [str], Callable, NoneType])* – Added in version 1.6.0.

  Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in *sklearn.metrics*, or any other user defined metric that looks like *sklearn.metrics*.

  If custom objective is also provided, then custom metric should implement the corresponding reverse link function.

  Unlike the *scoring* parameter commonly used in scikit-learn, when a callable object is provided, it’s assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

  For advanced usage on Early stopping like directly choosing to maximize instead of minimize, see *xgboost.callback.EarlyStopping*.

  See *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information.
```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

- **early_stopping_rounds** *(Optional [int])* – Added in version 1.6.0.
  - Activates early stopping. Validation metric needs to improve at least once in every `early_stopping_rounds` round(s) to continue training. Requires at least one item in `eval_set` in `fit()`.
  - If early stopping occurs, the model will have two additional attributes: `best_score` and `best_iteration`. These are used by the `predict()` and `apply()` methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the `iteration_range` in these inference methods. In addition, other utilities like model plotting can also use the entire model.
  - If you prefer to discard the trees after `best_iteration`, consider using the callback function `xgboost.callback.EarlyStopping`.
  - If there’s more than one item in `eval_set`, the last entry will be used for early stopping. If there’s more than one metric in `eval_metric`, the last metric will be used for early stopping.

- **callbacks** *(Optional [List [xgboost.callback.TrainingCallback]])* – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using `Callback API`.

```
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    reg = xgboost.XGBRegressor(**params, callbacks=callbacks)
    reg.fit(X, y)
```

- **kwargs** *(Optional [Any])* – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found here. Attempting to set a parameter via the constructor `args` and `**kwargs` dict simultaneously will result in a TypeError.

```
**kwargs unsupported by scikit-learn
**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed via this argument will interact properly with scikit-learn.
```
# Note

Custom objective function

A custom objective function can be provided for the `objective` parameter. In this case, it should have the signature `objective(y_true, y_pred) -> [grad, hess]` or `objective(y_true, y_pred, *, sample_weight) -> [grad, hess]`:

- **y_true**: array_like of shape [n_samples]
  The target values

- **y_pred**: array_like of shape [n_samples]
  The predicted values

- **sample_weight**:
  Optional sample weights.

- **grad**: array_like of shape [n_samples]
  The value of the gradient for each sample point.

- **hess**: array_like of shape [n_samples]
  The value of the second derivative for each sample point

---

**apply(X, iteration_range=None)**

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then `best_iteration` is used automatically.

**Parameters**

- **X** (array_like, shape=[n_samples, n_features]) – Input features matrix.

- **iteration_range** (Tuple[int | integer, int | integer] | None) – See `predict()`.

**Returns**

- **X_leaves** – For each datapoint x in X and for each tree, return the index of the leaf x ends up in. Leaves are numbered within \([0; 2^{\text{self.max_depth}+1})\), possibly with gaps in the numbering.

**Return type**

- array_like, shape=[n_samples, n_trees]

**property best_iteration**: int

The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is the first round, then `best_iteration` is 0.

**property best_score**: float

The best score obtained by early stopping.

**property coef_**: ndarray

Coefficients property

---

# Note

Coefficients are defined only for linear learners

Coefficients are only defined when the linear model is chosen as base learner (`booster=gblinear`). It is not defined for other base learner types, such as tree learners (`booster=gbtree`).
Returns

**coef_**

Return type

array of shape [n_features] or [n_classes, n_features]

evals_result()

Return the evaluation results.

If **eval_set** is passed to the **fit()** function, you can call **evals_result()** to get evaluation results for all passed **eval_sets**. When **eval_metric** is also passed to the **fit()** function, the **evals_result** will contain the **eval_metrics** passed to the **fit()** function.

The returned evaluation result is a dictionary:

```
{'validation_0': {'logloss': ['0.604835', '0.531479']},
 'validation_1': {'logloss': ['0.41965', '0.17686']}}
```

Return type

**evals_result**

property **feature_importances_** : **ndarray**

Feature importances property, return depends on **importance_type** parameter. When model trained with multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “average” is defined based on the importance type. For instance, if the importance type is “total_gain”, then the score is sum of loss change for each split from all trees.

Returns

- feature_importances_ (array of shape [n_features] except for multi-class)
- linear model, which returns an array with shape (n_features, n_classes)

property **feature_names_in_** : **ndarray**

Names of features seen during **fit()**. Defined only when X has feature names that are all strings.

**fit(X, y, *, sample_weight=None, base_margin=None, eval_set=None, verbose=True, xgb_model=None, sample_weight_eval_set=None, base_margin_eval_set=None, feature_weights=None)**

Fit gradient boosting classifier.

Note that calling **fit()** multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass **xgb_model** argument.

Parameters

- X (**Any**) – Feature matrix. See **Supported data structures for various XGBoost functions** for a list of supported types.

  When the **tree_method** is set to **hist**, internally, the **QuantileDMatrix** will be used instead of the **DMatrix** for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a numpy array on CPU but **cuda** is used for training, then the data is first processed on CPU then transferred to GPU.

- y (**Any**) – Labels

- sample_weight (**Any** | **None**) – instance weights

- base_margin (**Any** | **None**) – Global bias for each instance. See **Intercept** for details.
• **eval_set** *(Sequence [Tuple [Any, Any]] | None)* – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.

• **verbose** *(bool | int | None)* – If **verbose** is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If **verbose** is an integer, the evaluation metric is printed at each **verbose** boosting stage. The last boosting stage / the boosting stage found by using **early_stopping_rounds** is also printed.

• **xgb_model** *(Booster | str | XGBModel | None)* – file name of stored XGBoost model or ‘Booster’ instance XGBoost model to be loaded before training (allows training continuation).

• **sample_weight_eval_set** *(Sequence [Any] | None)* – A list of the form [L_1, L_2, ..., L_n], where each L_i is an array like object storing instance weights for the i-th validation set.

• **base_margin_eval_set** *(Sequence [Any] | None)* – A list of the form [M_1, M_2, ..., M_n], where each M_i is an array like object storing base margin for the i-th validation set.

• **feature_weights** *(Any | None)* – Weight for each feature, defines the probability of each feature being selected when colsample is being used. All values must be greater than 0, otherwise a **ValueError** is thrown.

---

**Return type**

**XGBRFClassifier**

---

**get_booster()**

Get the underlying xgboost Booster of this model.

This will raise an exception when fit was not called.

**Returns**

booster

**Return type**

a xgboost booster of underlying model

---

**get_metadata_routing()**

Get metadata routing of this object.

Please check **User Guide** on how the routing mechanism works.

**Returns**

routing – A **MetadataRequest** encapsulating routing information.

**Return type**

**MetadataRequest**

---

**get_num_boosting_rounds()**

Gets the number of xgboost boosting rounds.

**Return type**

int

---

**get_params**(deep=True)

Get parameters.

**Parameters**

**deep** *(bool)*
Return type

\[ \text{Dict[\text{str, Any}]} \]

get_xgb_params()
Get xgboost specific parameters.

Return type

\[ \text{Dict[\text{str, Any}]} \]

load_model(fname)
Load the model from a file or a bytestring.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

```python
model.load_model("model.json")
# or
model.load_model("model.ubj")
```

Parameters

- **fname** (str | bytearray | PathLike) – Input file name or memory buffer (see also save_raw)

Return type

None

property n_features_in_
Number of features seen during `fit()`.

predict(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)
Predict with X. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.

Note

This function is only thread safe for gbtree and dart.

Parameters

- **X** (Any) – Data to predict with.
- **output_margin** (bool) – Whether to output the raw untransformed margin value.
- **validate_features** (bool) – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
• **base_margin** *(Any | None)* – Global bias for each instance. See *Intercept* for details.

• **iteration_range** *(Tuple[int | integer, int | integer] | None)* – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying *iteration_range=(10, 20)*, then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

 Added in version 1.4.0.

**Return type**

prediction

**predict_proba** *(X, validate_features=True, base_margin=None, iteration_range=None)*

Predict the probability of each X example being of a given class. If the model is trained with early stopping, then *best_iteration* is used automatically. The estimator uses *inplace_predict* by default and falls back to using *DMatrix* if devices between the data and the estimator don’t match.

**Note**

This function is only thread safe for *gbtree* and *dart*.

**Parameters**

• **X** *(Any)* – Feature matrix. See *Supported data structures for various XGBoost functions* for a list of supported types.

• **validate_features** *(bool)* – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.

• **base_margin** *(Any | None)* – Global bias for each instance. See *Intercept* for details.

• **iteration_range** *(Tuple[int | integer, int | integer] | None)* – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying *iteration_range=(10, 20)*, then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

**Returns**

a numpy array of shape array-like of shape (n_samples, n_classes) with the probability of each data example being of a given class.

**Return type**

prediction

**save_model** *(fname)*

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See *Model IO* for more info.

```
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

**Parameters**

• **fname** *(str | PathLike)* – Output file name
Return type
None

score(X, y, sample_weight=None)
Return the mean accuracy on the given test data and labels.
In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each
sample that each label set be correctly predicted.

Parameters

- X (array-like of shape (n_samples, n_features)) – Test samples.
- y (array-like of shape (n_samples,) or (n_samples, n_outputs)) – True
  labels for X.
- sample_weight (array-like of shape (n_samples,), default=None) – Sam-
  ple weights.

Returns
score – Mean accuracy of self.predict(X) w.r.t. y.

Return type
float

set_fit_request(*, base_margin='$UNCHANGED$', base_margin_eval_set='$UNCHANGED$',
eval_set='$UNCHANGED$'.feature_weight_set='$UNCHANGED$'.sample_weight_set='$UNCHANGED$'.sample_weight_eval_set='$UNCHANGED$'.verbose_set='$UNCHANGED$'.xgb_model_set='$UNCHANGED$')
Request metadata passed to the fit method.
Note that this method is only relevant if enable_metadata_routing=True (see sklearn.
set_config()). Please see User Guide on how the routing mechanism works.
The options for each parameter are:

- True: metadata is requested, and passed to fit if provided. The request is ignored if metadata is not
  provided.
- False: metadata is not requested and the meta-estimator will not pass it to fit.
- None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- str: metadata should be passed to the meta-estimator with this given alias instead of the original
  name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows
you to change the request for some parameters and not others.
Added in version 1.3.

Note
This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used
inside a Pipeline. Otherwise it has no effect.

Parameters

- base_margin (str, True, False, or None, default=sklearn.utils.
  metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter
  in fit.
- **base_margin_eval_set**  
  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin_eval_set parameter in fit.

- **eval_set**  
  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for eval_set parameter in fit.

- **feature_weights**  
  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for feature_weights parameter in fit.

- **sample_weight**  
  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight parameter in fit.

- **sample_weight_eval_set**  
  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight_eval_set parameter in fit.

- **verbose**  
  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for verbose parameter in fit.

- **xgb_model**  
  (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for xgb_model parameter in fit.

- **self** (XGBRFClassifier)

  Returns
  
  self – The updated object.

  Return type
  
  object

**set_params(**params)**

Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

**Return type**

self

**Parameters**

**params** (Any)

**set_predict_proba_request(**, base_margin='UNCHANGED', iteration_range='UNCHANGED', validate_features='UNCHANGED')**

Request metadata passed to the predict_proba method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to predict_proba if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to predict_proba.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
• str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

**Parameters**

- **base_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict_proba.
- **iteration_range** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict_proba.
- **validate_features** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict_proba.

**self** (XGBRFClassifier)

**Returns**

self – The updated object.

**Return type**

object

`set_predict_request(*, base_margin='$UNCHANGED$', iteration_range='$UNCHANGED$', output_margin='$UNCHANGED$', validate_features='$UNCHANGED$')`

Request metadata passed to the predict method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to predict if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to predict.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.
Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

- **base_margin** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for base_margin parameter in predict.

- **iteration_range** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for iteration_range parameter in predict.

- **output_margin** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for output_margin parameter in predict.

- **validate_features** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for validate_features parameter in predict.

- **self** *(XGBRFClassifier)*

Returns

self – The updated object.

Return type

object

**set_score_request(**, **sample_weight=\$UNCHANGED\$)**

Request metadata passed to the score method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to score if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to score.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.
Parameters

- **sample_weight** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight parameter in score.
- **self** *(XGBRFClassifier)*

Returns

self – The updated object.

Return type

object

Plotting API

Plotting Library.

```python
xgboost.plot_importance(booster, ax=None, height=0.2, xlim=None, ylim=None, title='Feature importance', xlabel='F score', ylabel='Features', fmap='', importance_type='weight', max_num_features=None, grid=True, show_values=True, values_format='{v}', **kwargs)
```

Plot importance based on fitted trees.

Parameters

- **booster** *(XGBModel | Booster | dict)* – Booster or XGBModel instance, or dict taken by Booster.get_fscore()
- **ax** *(matplotlib Axes)* – Target axes instance. If None, new figure and axes will be created.
- **grid** *(bool)* – Turn the axes grids on or off. Default is True (On).
- **importance_type** *(str)* – How the importance is calculated: either “weight”, “gain”, or “cover”
  - ”weight” is the number of times a feature appears in a tree
  - ”gain” is the average gain of splits which use the feature
  - ”cover” is the average coverage of splits which use the feature where coverage is defined as the number of samples affected by the split
- **max_num_features** *(int | None)* – Maximum number of top features displayed on plot. If None, all features will be displayed.
- **height** *(float)* – Bar height, passed to ax.barh()
- **xlim** *(tuple | None)* – Tuple passed to axes.xlim()
- **ylim** *(tuple | None)* – Tuple passed to axes ylim()
- **title** *(str)* – Axes title. To disable, pass None.
- **xlabel** *(str)* – X axis title label. To disable, pass None.
- **ylabel** *(str)* – Y axis title label. To disable, pass None.
- **fmap** *(str | PathLike)* – The name of feature map file.
- **show_values** *(bool)* – Show values on plot. To disable, pass False.
• **values_format** *(str)* – Format string for values. “v” will be replaced by the value of the feature importance. e.g. Pass “{v:.2f}” in order to limit the number of digits after the decimal point to two, for each value printed on the graph.

• **kwargs** *(Any)* – Other keywords passed to `ax.barh()`

Returns

`ax`

Return type

`matplotlib Axes`

`xgboost.plot_tree(booster, fmap='', num_trees=0, rankdir=None, ax=None, **kwargs)`

Plot specified tree.

Parameters

• **booster** *(Booster, XGBModel)* – Booster or XGBModel instance

• **fmap** *(str (optional))* – The name of feature map file

• **num_trees** *(int, default 0)* – Specify the ordinal number of target tree

• **rankdir** *(str, default "TB")* – Passed to graphviz via `graph_attr`

• **ax** *(matplotlib Axes, default None)* – Target axes instance. If None, new figure and axes will be created.

• **kwargs** *(Any)* – Other keywords passed to `to_graphviz`

Returns

`ax`

Return type

`matplotlib Axes`

`xgboost.to_graphviz(booster, fmap='', num_trees=0, rankdir=None, yes_color=None, no_color=None, condition_node_params=None, leaf_node_params=None, **kwargs)`

Convert specified tree to graphviz instance. IPython can automatically plot the returned graphviz instance. Otherwise, you should call `.render()` method of the returned graphviz instance.

Parameters

• **booster** *(Booster / XGBModel)* – Booster or XGBModel instance

• **fmap** *(str / PathLike)* – The name of feature map file

• **num_trees** *(int)* – Specify the ordinal number of target tree

• **rankdir** *(str / None)* – Passed to graphviz via `graph_attr`

• **yes_color** *(str / None)* – Edge color when meets the node condition.

• **no_color** *(str / None)* – Edge color when doesn’t meet the node condition.

• **condition_node_params** *(dict / None)* – Condition node configuration for for graphviz. Example:

```json
{
    'shape': 'box',
    'style': 'filled,rounded',
    'fillcolor': '#78bceb'
}
```

• **leaf_node_params** *(dict / None)* – Leaf node configuration for graphviz. Example:
xgboost, Release 2.1.1

```json
{
'shape': 'box',
'style': 'filled',
'fillcolor': '#e48038'
}
```

- **kwargs (Any)** – Other keywords passed to graphviz graph_attr, e.g. graph [ {key} = {value} ]

**Returns**

graph

**Return type**

graphviz.Source

---

**Callback API**

Callback library containing training routines. See *Callback Functions* for a quick introduction.

**class xgboost.callback.TrainingCallback**

Interface for training callback.

Added in version 1.3.0.

**after_iteration(model, epoch, evals_log)**

Run after each iteration. Returns True when training should stop.

**Parameters**

- **model (Any)** – Either a Booster object or a CVPack if the cv function in xgboost is being used.
- **epoch (int)** – The current training iteration.
- **evals_log (Dict[str, Dict[str, List[float]] | List[Tuple[float, float]]])** – A dictionary containing the evaluation history:

  ```json
  {"data_name": {"metric_name": [0.5, ...]}}
  ```

**Return type**

bool

**after_training(model)**

Run after training is finished.

**Parameters**

- **model (Any)**

**Return type**

Any

**before_iteration(model, epoch, evals_log)**

Run before each iteration. Returns True when training should stop. See *after_iteration()* for details.

**Parameters**

- **model (Any)**
- **epoch (int)**
before_training(model)
Run before training starts.

Parameters

• model (Any)

Return type

Any

class xgboost.callback.EvaluationMonitor(
    rank=0, period=1, show_stdv=False)
Bases: TrainingCallback
Print the evaluation result at each iteration.
Added in version 1.3.0.

Parameters

• rank (int) – Which worker should be used for printing the result.
• period (int) – How many epoches between printing.
• show_stdv (bool) – Used in cv to show standard deviation. Users should not specify it.

after_iteration(model, epoch, evals_log)
Run after each iteration. Returns True when training should stop.

Parameters

• model (Any) – Either a Booster object or a CVPack if the cv function in xgboost is being used.
• epoch (int) – The current training iteration.
• evals_log (Dict[str, Dict[str, List[float] | List[Tuple[float, float]]]]) – A dictionary containing the evaluation history:

{"data_name": {"metric_name": [0.5, ...]}}

Return type

bool

after_training(model)
Run after training is finished.

Parameters

• model (Any)

Return type

Any

class xgboost.callback.EarlyStopping(
    rounds, metric_name=None, data_name=None, maximize=None,
    save_best=False, min_delta=0.0)
Bases: TrainingCallback
Callback function for early stopping
Added in version 1.3.0.
Parameters

• **rounds** (*int*) – Early stopping rounds.
• **metric_name** (*str | None*) – Name of metric that is used for early stopping.
• **data_name** (*str | None*) – Name of dataset that is used for early stopping.
• **maximize** (*bool | None*) – Whether to maximize evaluation metric. None means auto (discouraged).
• **save_best** (*bool | None*) – Whether training should return the best model or the last model.
• **min_delta** (*float*) – Added in version 1.5.0. Minimum absolute change in score to be qualified as an improvement.

Examples

```python
es = xgboost.callback.EarlyStopping(
    rounds=2,
    min_delta=1e-3,
    save_best=True,
    maximize=False,
    data_name="validation_0",
    metric_name="mlogloss",
)
clf = xgboost.XGBClassifier(tree_method="hist", device="cuda", callbacks=[es])
X, y = load_digits(return_X_y=True)
clf.fit(X, y, eval_set=[(X, y)])
```

**after_iteration** *(model, epoch, evals_log)*

Run after each iteration. Returns *True* when training should stop.

Parameters

• **model** (*Any*) – Either a *Booster* object or a CVPack if the cv function in xgboost is being used.
• **epoch** (*int*) – The current training iteration.
• **evals_log** (*Dict[str, Dict[str, List[float] | List[Tuple[float, float]]]]*) – A dictionary containing the evaluation history:

```python
{"data_name": {"metric_name": [0.5, ...]}}
```

Return type

*bool*

**after_training** *(model)*

Run after training is finished.

Parameters

• **model** (*Any*)

Return type

*Any*
before_training(model)
Run before training starts.

Parameters
model (Any)

Return type
Any

class xgboost.callback.LearningRateScheduler(learning_rates)
Bases: TrainingCallback
Callback function for scheduling learning rate.
Added in version 1.3.0.

Parameters
learning_rates (Callable[[int], float] | Sequence[float]) – If it’s a callable object, then it should accept an integer parameter epoch and returns the corresponding learning rate. Otherwise it should be a sequence like list or tuple with the same size of boosting rounds.

after_iteration(model, epoch, evals_log)
Run after each iteration. Returns True when training should stop.

Parameters
• model (Any) – Either a Booster object or a CVPack if the cv function in xgboost is being used.
• epoch (int) – The current training iteration.
• evals_log (Dict[str, Dict[str, List[float] | List[Tuple[float, float]]]]) – A dictionary containing the evaluation history:

    "data_name": {"metric_name": [0.5, ...]}

Return type
bool

class xgboost.callback.TrainingCheckPoint(directory, name='model', as_pickle=False, interval=100)
Bases: TrainingCallback
Checkpointing operation. Users are encouraged to create their own callbacks for checkpoint as XGBoost doesn’t handle distributed file systems. When checkpointing on distributed systems, be sure to know the rank of the worker to avoid multiple workers checkpointing to the same place.
Added in version 1.3.0.
Since XGBoost 2.1.0, the default format is changed to UBJSON.

Parameters
• directory (str | PathLike) – Output model directory.
• name (str) – Pattern of output model file. Models will be saved as name_0.ubj, name_1.ubj, name_2.ubj ....
• as_pickle (bool) – When set to True, all training parameters will be saved in pickle format, instead of saving only the model.
• interval (int) – Interval of checkpointing. Checkpointing is slow so setting a larger number can reduce performance hit.
**after_iteration**(*model*, *epoch*, *evals_log*)

Run after each iteration. Returns True when training should stop.

**Parameters**

- **model** (*Any*) – Either a Booster object or a CVPack if the cv function in xgboost is being used.
- **epoch** (*int*) – The current training iteration.
- **evals_log** (*Dict[str, Dict[str, List[float] | List[Tuple[float, float]]]]*) – A dictionary containing the evaluation history:

```python
{"data_name": {"metric_name": [0.5, ...]}}
```

**Return type**

`bool`

**before_training**(*model*)

Run before training starts.

**Parameters**

- **model** (*Any*)

**Return type**

`Any`

---

**Dask API**

**Dask extensions for distributed training**

See [Distributed XGBoost with Dask](#) for simple tutorial. Also [XGBoost Dask Feature Walkthrough](#) for some examples.

There are two sets of APIs in this module, one is the functional API including train and predict methods. Another is stateful Scikit-Learner wrapper inherited from single-node Scikit-Learn interface.

The implementation is heavily influenced by dask_xgboost: [https://github.com/dask/dask-xgboost](https://github.com/dask/dask-xgboost)

**Optional dask configuration**

- **xgboost.scheduler_address**: Specify the scheduler address, see [Troubleshooting](#).

  Added in version 1.6.0.

```python
dask.config.set({"xgboost.scheduler_address": "192.0.0.100"})
# We can also specify the port.
dask.config.set({"xgboost.scheduler_address": "192.0.0.100:12345"})
```

**class xgboost.dask.DaskDMatrix**(*client*, *data*, *label=None*, *weight=None*, *base_margin=None*, *missing=None*, *silent=False*, *feature_names=None*, *feature_types=None*, *group=None*, *qid=None*, *label_lower_bound=None*, *label_upper_bound=None*, *feature_weights=None*, *enable_categorical=False*)

**Bases**: `object`
DMatrix holding on references to Dask DataFrame or Dask Array. Constructing a DaskDMatrix forces all lazy computation to be carried out. Wait for the input data explicitly if you want to see actual computation of constructing DaskDMatrix.

See doc for xgboost.DMatrix constructor for other parameters. DaskDMatrix accepts only dask collection.

Note

DaskDMatrix does not repartition or move data between workers. It’s the caller’s responsibility to balance the data.

Added in version 1.0.0.

Parameters

- **client** (`distributed.Client`) – Specify the dask client used for training. Use default client returned from dask if it’s set to None.
- **data** (`da.Array` | `dd.DataFrame`)
- **label** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`)
- **weight** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`)
- **base_margin** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`)
- **missing** (`float` | `None`)
- **silent** (`bool`)
- **feature_names** (`Sequence[str]` | `None`)
- **feature_types** (`Sequence[str]` | `None`)
- **group** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`)
- **qid** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`)
- **label_lower_bound** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`)
- **label_upper_bound** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`)
- **feature_weights** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`)
- **enable_categorical** (`bool`)

**num_col()**

Get the number of columns (features) in the DMatrix.

**Return type**

number of columns

class xgboost.dask.DaskQuantileDMatrix(client, data, label=None, *, weight=None, base_margin=None, missing=None, silent=False, feature_names=None, feature_types=None, max_bin=None, ref=None, group=None, qid=None, label_lower_bound=None, label_upper_bound=None, feature_weights=None, enable_categorical=False)

Bases: DaskDMatrix

A dask version of QuantileDMatrix.

Parameters

- **client** (`distributed.Client`)

1.10. XGBoost Python Package
• **data** (da.Array | dd.DataFrame)
• **label** (da.Array | dd.DataFrame | dd.Series | None)
• **weight** (da.Array | dd.DataFrame | dd.Series | None)
• **base_margin** (da.Array | dd.DataFrame | dd.Series | None)
• **missing** (float | None)
• **silent** (bool)
• **feature_names** (Sequence[str] | None)
• **feature_types** (Any | List[Any] | None)
• **max_bin** (int | None)
• **ref** (DMatrix | None)
• **group** (da.Array | dd.DataFrame | dd.Series | None)
• **qid** (da.Array | dd.DataFrame | dd.Series | None)
• **label_lower_bound** (da.Array | dd.DataFrame | dd.Series | None)
• **label_upper_bound** (da.Array | dd.DataFrame | dd.Series | None)
• **feature_weights** (da.Array | dd.DataFrame | dd.Series | None)
• **enable_categorical** (bool)

**num_col()**

Get the number of columns (features) in the DMatrix.

**Return type**

number of columns

```
xgboost.dask.train(client, params, dtrain, num_boost_round=10, *, evals=None, obj=None, feval=None, early_stopping_rounds=None, xgb_model=None, verbose_eval=True, callbacks=None, custom_metric=None)
```

Train XGBoost model.

Added in version 1.0.0.

**Note**

Other parameters are the same as `xgboost.train()` except for `evals_result`, which is returned as part of function return value instead of argument.

**Parameters**

• **client** (distributed.Client) – Specify the dask client used for training. Use default client returned from dask if it’s set to None.
• **params** (Dict[str, Any])
• **dtrain** (DaskDMatrix)
• **num_boost_round** (int)
• **evals** (Sequence[Tuple[DaskDMatrix, str]] | None)
• **obj** (Callable[[ndarray, DMatrix], Tuple[ndarray, ndarray]] | None)
• feval (Callable[[ndarray, DMatrix], Tuple[str, float]] | None)
• early_stopping_rounds (int | None)
• xgb_model (Booster | None)
• verbose_eval (int | bool)
• callbacks (Sequence[TrainingCallback] | None)
• custom_metric (Callable[[ndarray, DMatrix], Tuple[str, float]] | None)

Returns

results – A dictionary containing trained booster and evaluation history. history field is the same as eval_result from xgboost.train.

```python
dict

xgboost.Booster,
'history': {'train': {'logloss': ['0.48253', '0.35953']},
'eval': {'logloss': ['0.480385', '0.357756']}}}}
```

Return type
dict

xgboost.dask.predict(client, model, data, output_margin=False, missing=nan, pred_leaf=False, pred_contribs=False, approx_contribs=False, pred_interactions=False, validate_features=True, iteration_range=(0, 0), strict_shape=False)

Run prediction with a trained booster.

**Note**

Using inplace_predict might be faster when some features are not needed. See xgboost.Booster.predict() for details on various parameters. When output has more than 2 dimensions (shap value, leaf with strict_shape), input should be da.Array or DaskDMatrix.

Added in version 1.0.0.

**Parameters**

- client (distributed.Client | None) – Specify the dask client used for training. Use default client returned from dask if it's set to None.
- model (TrainReturnT | Booster | distributed.Future) – The trained model. It can be a distributed.Future so user can pre-scatter it onto all workers.
- data (DaskDMatrix | da.Array | dd.DataFrame) – Input data used for prediction. When input is a dataframe object, prediction output is a series.
- missing (float) – Used when input data is not DaskDMatrix. Specify the value considered as missing.
- output_margin (bool)
- pred_leaf (bool)
- pred_contribs (bool)
- approx_contribs (bool)
- pred_interactions (bool)
- validate_features (bool)
• **iteration_range** *(Tuple[int | integer, int | integer]*)
• **strict_shape** *(bool)*

**Returns**

- **prediction** – When input data is `dask.array.Array` or `DaskDMatrix`, the return value is an array, when input data is `dask.dataframe.DataFrame`, return value can be `dask.dataframe.Series`, `dask.dataframe.DataFrame`, depending on the output shape.

**Return type**

dask.array.Array/dask.dataframe.Series

```python
xgboost.dask.inplace_predict(client, model, data, iteration_range=(0, 0), predict_type='value', missing=nan, validate_features=True, base_margin=None, strict_shape=False)
```

Inplace prediction. See doc in `xgboost.Booster.inplace_predict()` for details.

Added in version 1.1.0.

**Parameters**

- **client** *(distributed.Client | None)* – Specify the dask client used for training. Use default client returned from dask if it’s set to None.
- **model** *(TrainReturnT | Booster | distributed.Future)* – See `xgboost.dask.predict()` for details.
- **iteration_range** *(Tuple[int | integer, int | integer])* – See `xgboost.Booster.predict()` for details.
- **missing** *(float)* – Value in the input data which needs to be present as a missing value. If None, defaults to np.nan.
  
  Added in version 1.4.0.
- **strict_shape** *(bool)* – See `xgboost.Booster.predict()` for details.
  
  Added in version 1.4.0.
- **validate_features** *(bool)*

**Returns**

- **prediction** – When input data is `dask.array.Array`, the return value is an array, when input data is `dask.dataframe.DataFrame`, return value can be `dask.dataframe.Series`, `dask.dataframe.DataFrame`, depending on the output shape.

**Return type**

prediction
class xgboost.dask.DaskXGBClassifier(max_depth=None, max_leaves=None, max_bin=None,

early_stopping_rounds=None, callbacks=None,**kwargs)

Bases: DaskScikitLearnBase, ClassifierMixin

Implementation of the scikit-learn API for XGBoost classification. See Using the Scikit-Learn Estimator Interface for more information.

Parameters

- **n_estimators (Optional [int])** – Number of gradient boosted trees. Equivalent to number of boosting rounds.
- **max_depth (Optional [int])** – Maximum tree depth for base learners.
- **max_leaves (Optional [int])** – Maximum number of leaves; 0 indicates no limit.
- **max_bin (Optional [int])** – If using histogram-based algorithm, maximum number of bins per feature
- **grow_policy (Optional [str])** – Tree growing policy.
  - depthwise: Favors splitting at nodes closest to the node,
  - lossguide: Favors splitting at nodes with highest loss change.
- **learning_rate (Optional [float])** – Boosting learning rate (xgb’s “eta”)
- **verbosity (Optional [int])** – The degree of verbosity. Valid values are 0 (silent) - 3 (debug).
- **objective (Union [str, xgboost.sklearn._SklObjWProto, Callable[[Any, Any], Tuple[numpy.ndarray, numpy.ndarray]], NoneType])** – Specify the learning task and the corresponding learning objective or a custom objective function to be used.

For custom objective, see Custom Objective and Evaluation Metric and Custom objective and metric for more information, along with the end note for function signatures.

- **booster (Optional [str])** – Specify which booster to use: gbtree, gblinear or dart.
- **tree_method (Optional [str])** – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available. It’s recommended to study this option from the parameters document tree method
- **n_jobs (Optional [int])** – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.
• **gamma** *(Optional*[float]*) – (min_split_loss) Minimum loss reduction required to make a further partition on a leaf node of the tree.

• **min_child_weight** *(Optional*[float]*) – Minimum sum of instance weight(hessian) needed in a child.

• **max_delta_step** *(Optional*[float]*) – Maximum delta step we allow each tree’s weight estimation to be.

• **subsample** *(Optional*[float]*) – Subsample ratio of the training instance.

• **sampling_method** *(Optional*[str]*) – Sampling method. Used only by the GPU version of hist tree method.
  - uniform: Select random training instances uniformly.
  - gradient_based: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)

• **colsample_bytree** *(Optional*[float]*) – Subsample ratio of columns when constructing each tree.

• **colsample_bylevel** *(Optional*[float]*) – Subsample ratio of columns for each level.

• **colsample_bynode** *(Optional*[float]*) – Subsample ratio of columns for each split.

• **reg_alpha** *(Optional*[float]*) – L1 regularization term on weights (xgb’s alpha).

• **reg_lambda** *(Optional*[float]*) – L2 regularization term on weights (xgb’s lambda).

• **scale_pos_weight** *(Optional*[float]*) – Balancing of positive and negative weights.

• **base_score** *(Optional*[float]*) – The initial prediction score of all instances, global bias.

• **random_state** *(Union*[numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType]*) – Random number seed.

    Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.

• **missing** *(float)* – Value in the data which needs to be present as a missing value. Default to *numpy.nan*.

• **num_parallel_tree** *(Optional*[int]*) – Used for boosting random forest.

• **monotone_constraints** *(Union*[Dict*[str, int], str, NoneType]*) – Constraint of variable monotonicity. See tutorial for more information.

• **interaction_constraints** *(Union*[str, List*[Tuple*[str]]], NoneType]*) – Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nested list, e.g. `[[0, 1], [2, 3, 4]]`, where each inner list is a group of indices of features that are allowed to interact with each other. See tutorial for more information.

• **importance_type** *(Optional*[str]*) – The feature importance type for the feature_importances_ property:
  - For tree model, it’s either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  - For linear model, only “weight” is defined and it’s the normalized coefficients without bias.
• **device** *(Optional [str])* – Added in version 2.0.0.
  
  Device ordinal, available options are *cpu, cuda, and gpu*.

• **validate_parameters** *(Optional [bool])* – Give warnings for unknown parameter.

• **enable_categorical** *(bool)* – See the same parameter of *DMatrix* for details.

• **feature_types** *(Optional [Sequence [str]])* – Added in version 1.7.0.
  
  Used for specifying feature types without constructing a dataframe. See *DMatrix* for details.

• **max_cat_to_onehot** *(Optional [int])* – Added in version 1.6.0.

  **Note**

  This parameter is experimental

  A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, *enable_categorical* needs to be set to have categorical feature support. See *Categorical Data* and *Parameters for Categorical Feature* for details.

• **max_cat_threshold** *(Optional [int])* – Added in version 1.7.0.

  **Note**

  This parameter is experimental

  Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, *enable_categorical* needs to be set to have categorical feature support. See *Categorical Data* and *Parameters for Categorical Feature* for details.

• **multi_strategy** *(Optional [str])* – Added in version 2.0.0.

  **Note**

  This parameter is working-in-progress.

  The strategy used for training multi-target models, including multi-target regression and multi-class classification. See *Multiple Outputs* for more information.

  – one_output_per_tree: One model for each target.
  

• **eval_metric** *(Union [str, List [str], Callable, NoneType])* – Added in version 1.6.0.

  Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in *sklearn.metrics*, or any other user defined metric that looks like *sklearn.metrics*.

  If custom objective is also provided, then custom metric should implement the corresponding reverse link function.
Unlike the *scoring* parameter commonly used in scikit-learn, when a callable object is provided, it's assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

For advanced usage on Early stopping like directly choosing to maximize instead of minimizing, see `xgboost.callback.EarlyStopping`.

See *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information.

```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

- **early_stopping_rounds** (*Optional*[int]) – Added in version 1.6.0.
  - Activates early stopping. Validation metric needs to improve at least once in every `early_stopping_rounds` round(s) to continue training. Requires at least one item in `eval_set` in `fit()`.
  - If early stopping occurs, the model will have two additional attributes: `best_score` and `best_iteration`. These are used by the `predict()` and `apply()` methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the `iteration_range` in these inference methods. In addition, other utilities like model plotting can also use the entire model.
  - If you prefer to discard the trees after `best_iteration`, consider using the callback function `xgboost.callback.EarlyStopping`.
  - If there's more than one item in `eval_set`, the last entry will be used for early stopping. If there's more than one metric in `eval_metric`, the last metric will be used for early stopping.

- **callbacks** (*Optional*[List*[xgboost.callback.TrainingCallback]*) – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using *Callback API*.

```
# Note
States in callback are not preserved during training, which means callback objects cannot be reused for multiple training sessions without reinitialization or deepcopy.
```

```python
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    reg = xgboost.XGBRegressor(**params, callbacks=callbacks)
    reg.fit(X, y)
```

- **kwargs** (*Optional*[Any]) – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found [here](#). Attempting to set a parameter via the constructor args and **kwargs dict simultaneously will result in a TypeError.
apply($X$, $iteration\_range=None$)

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then $best\_iteration$ is used automatically.

Parameters

- $X$ (array_like, shape=[n_samples, n_features]) – Input features matrix.
- $iteration\_range$ (Tuple[int | integer, int | integer] | None) – See predict().

Returns

$X\_leaves$ – For each datapoint $x$ in $X$ and for each tree, return the index of the leaf $x$ ends up in. Leaves are numbered within $[0; 2^{*(self\_max\_depth+1)}$, possibly with gaps in the numbering.

Return type

array_like, shape=[n_samples, n_trees]

property best\_iteration: int

The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is the first round, then best\_iteration is 0.

property best\_score: float

The best score obtained by early stopping.

property client: distributed.Client

The dask client used in this model. The Client object can not be serialized for transmission, so if task is launched from a worker instead of directly from the client process, this attribute needs to be set at that worker.

property coef_: ndarray

Coefficients property

Note

**kwargs unsupported by scikit-learn

**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed via this argument will interact properly with scikit-learn.

Coefficients are defined only for linear learners

Coefficients are only defined when the linear model is chosen as base learner (booster=gblinear). It is not defined for other base learner types, such as tree learners (booster=gbtree).
`evals_result()`

Return the evaluation results.

If `eval_set` is passed to the `fit()` function, you can call `evals_result()` to get evaluation results for all passed `eval_sets`. When `eval_metric` is also passed to the `fit()` function, the `evals_result` will contain the `eval_metrics` passed to the `fit()` function.

The returned evaluation result is a dictionary:

```python
{'validation_0': {'logloss': [0.604835, 0.531479]},
 'validation_1': {'logloss': [0.41965, 0.17686]}}
```

Return type

`evals_result`

property `feature_importances_`: `ndarray`

Feature importances property, return depends on `importance_type` parameter. When model trained with multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “average” is defined based on the importance type. For instance, if the importance type is “total_gain”, then the score is sum of loss change for each split from all trees.

Returns

- `feature_importances_` (array of shape `[n_features]` except for multi-class)
- linear model, which returns an array with shape `(n_features, n_classes)`

property `feature_names_in_`: `ndarray`

Names of features seen during `fit()`. Defined only when `X` has feature names that are all strings.

`fit(X, y, *, sample_weight=None, base_margin=None, eval_set=None, verbose=True, xgb_model=None, sample_weight_eval_set=None, base_margin_eval_set=None, feature_weights=None)`

Fit gradient boosting model.

Note that calling `fit()` multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass `xgb_model` argument.

Parameters

- `X` *(`da.Array` | `dd.DataFrame`)* – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.

  When the `tree_method` is set to `hist`, internally, the `QuantileDMatrix` will be used instead of the `DMatrix` for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a numpy array on CPU but cuda is used for training, then the data is first processed on CPU then transferred to GPU.

- `eval_set` *(Sequence[`Tuple[da.Array, dd.DataFrame, dd.Series]`, `None`])* – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.
• **verbose** (*int* | *bool*) – If `verbose` is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If `verbose` is an integer, the evaluation metric is printed at each `verbose` boosting stage. The last boosting stage / the boosting stage found by using `early_stopping_rounds` is also printed.

• **xgb_model** (*Booster* | *XGBModel* | *None*) – file name of stored XGBoost model or ‘Booster’ instance XGBoost model to be loaded before training (allows training continuation).

• **sample_weight_eval_set** (*Sequence*[`da.Array` | `dd.DataFrame` | `dd.Series`] | *None*) – A list of the form `[L_1, L_2, ..., L_n]`, where each `L_i` is an array like object storing instance weights for the i-th validation set.

• **base_margin_eval_set** (*Sequence*[`da.Array` | `dd.DataFrame` | `dd.Series`] | *None*) – A list of the form `[M_1, M_2, ..., M_n]`, where each `M_i` is an array like object storing base margin for the i-th validation set.

• **feature_weights** (*da.Array* | *dd.DataFrame* | *dd.Series* | *None*) – Weight for each feature, defines the probability of each feature being selected when `colsample` is being used. All values must be greater than 0, otherwise a `ValueError` is thrown.

Return type

`DaskXGBClassifier`

**get_booster()**

Get the underlying xgboost Booster of this model.

This will raise an exception when fit was not called

Returns

booster

Return type

a xgboost booster of underlying model

**get_metadata_routing()**

Get metadata routing of this object.

Please check User Guide on how the routing mechanism works.

Returns

routing – A `MetadataRequest` encapsulating routing information.

Return type

`.MetadataRequest`

**get_num_boosting_rounds()**

Gets the number of xgboost boosting rounds.

Return type

int

**get_params**(deep=**True**)  
Get parameters.

Parameters

deep (*bool*)

Return type

`Dict[str, Any]`
get_xgb_params()

Get xgboost specific parameters.

Return type

Dict[str, Any]

property intercept_: ndarray

Intercept (bias) property

For tree-based model, the returned value is the base_score.

Returns

intercept_

Return type

array of shape (1,) or [n_classes]

load_model(fname)

Load the model from a file or a bytarray.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

model.load_model("model.json")

# or
model.load_model("model.ubj")

Parameters

fname (str | bytearray | PathLike) – Input file name or memory buffer(see also save_raw)

Return type

None

property n_features_in_: int

Number of features seen during fit().

predict(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)

Predict with X. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.

Note

This function is only thread safe for gbtree and dart.

Parameters

• X (da.Array | dd.DataFrame) – Data to predict with.
• output_margin (bool) – Whether to output the raw untransformed margin value.
• validate_features (bool) – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
• base_margin (da.Array | dd.DataFrame | dd.Series | None) – Global bias for each instance. See Intercept for details.
• **iteration_range** *(Tuple[int | integer, int | integer] | None) – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying **iteration_range**=(10, 20), then only the forests built during [10, 20) (half open set) rounds are used in this prediction.*

  Added in version 1.4.0.

**Return type**

prediction

**predict_proba** *(X, validate_features=True, base_margin=None, iteration_range=None)*

Predict the probability of each X example being of a given class. If the model is trained with early stopping, then **best_iteration** is used automatically. The estimator uses **inplace_predict** by default and falls back to using **DMatrix** if devices between the data and the estimator don’t match.

**Note**

This function is only thread safe for **gbtree** and **dart**.

**Parameters**

• **X** *(da.Array | dd.DataFrame | dd.Series) – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.*

• **validate_features** *(bool) – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.*

• **base_margin** *(da.Array | dd.DataFrame | dd.Series | None) – Global bias for each instance. See **Intercept** for details.*

• **iteration_range** *(Tuple[int | integer, int | integer] | None) – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying **iteration_range**=(10, 20), then only the forests built during [10, 20) (half open set) rounds are used in this prediction.*

**Returns**

a numpy array of shape array-like of shape (n_samples, n_classes) with the probability of each data example being of a given class.

**Return type**

prediction

**save_model** *(fname)*

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

```
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

**Parameters**

• **fname** *(str | PathLike) – Output file name*
**Return type**
None

**score**(*X, y, sample_weight=None*)
Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**
- *X* (array-like of shape (n_samples, n_features)) – Test samples.
- *y* (array-like of shape (n_samples,) or (n_samples, n_outputs)) – True labels for *X*.
- *sample_weight* (array-like of shape (n_samples,), default=None) – Sample weights.

**Returns**
- *score* – Mean accuracy of `self.predict(X)` w.r.t. *y*.

**Return type**
float

**set_fit_request**(*, base_margin='UNCHANGED', base_margin_eval_set='UNCHANGED', eval_set='UNCHANGED', feature_weights='UNCHANGED', sample_weight='UNCHANGED', sample_weight_eval_set='UNCHANGED', verbose='UNCHANGED', xgb_model='UNCHANGED')
Request metadata passed to the `fit` method.

Note that this method is only relevant if `enable_metadata_routing=True` (see `sklearn.set_config()`). Please see User Guide on how the routing mechanism works.

The options for each parameter are:
- **True**: metadata is requested, and passed to `fit` if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to `fit`.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (`sklearn.utils.metadata_routing.UNCHANGED`) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

### Note
This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a `Pipeline`. Otherwise it has no effect.

**Parameters**
- **base_margin** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for `base_margin` parameter in `fit`. 
• `base_margin_eval_set` *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for base_margin_eval_set parameter in fit.

• `eval_set` *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for eval_set parameter in fit.

• `feature_weights` *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for feature_weights parameter in fit.

• `sample_weight` *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight parameter in fit.

• `sample_weight_eval_set` *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight_eval_set parameter in fit.

• `verbose` *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for verbose parameter in fit.

• `xgb_model` *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for xgb_model parameter in fit.

• `self` *(DaskXGBClassifier)*

Returns
self – The updated object.

Return type
object

`set_params(**params)`
Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

Return type
self

Parameters
params *(Any)*

`set_predict_proba_request(*, base_margin='UNCHANGED', iteration_range='UNCHANGED', validate_features='UNCHANGED')`  
Request metadata passed to the predict_proba method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• True: metadata is requested, and passed to predict_proba if provided. The request is ignored if metadata is not provided.

• False: metadata is not requested and the meta-estimator will not pass it to predict_proba.

• None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
• str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

Note
This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

• base_margin (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict_proba.

• iteration_range (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict_proba.

• validate_features (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict_proba.

• self (DaskXGBClassifier)

Returns

self – The updated object.

Return type

object

set_predict_request(*, base_margin='UNCHANGED', iteration_range='UNCHANGED', output_margin='UNCHANGED', validate_features='UNCHANGED')

Request metadata passed to the predict method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• True: metadata is requested, and passed to predict if provided. The request is ignored if metadata is not provided.

• False: metadata is not requested and the meta-estimator will not pass it to predict.

• None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.

• str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.
### Parameters

- **base_margin**  
  
  `(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict.

- **iteration_range**  
  
  `(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict.

- **output_margin**  
  
  `(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for output_margin parameter in predict.

- **validate_features**  
  
  `(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict.

- **self**  
  
  `DaskXGBClassifier`

### Returns

- **self**  
  
  The updated object.

### Return type

- **object**

---

#### set_score_request(*, sample_weight='UNCHANGED')

Request metadata passed to the `score` method.

Note that this method is only relevant if `enable_metadata_routing=True` (see `sklearn.set_config()`). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to `score` if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to `score`.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.
Parameters

- **sample_weight** *(str, True, False, or None, default=sklearn.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight parameter in score.

- **self** *(DaskXGBClassifier)*

Returns

**self** – The updated object.

Return type

**object**

class xgboost.dask.DaskXGBRegressor(max_depth=None, max_leaves=None, max_bin=None, grow_policy=None, learning_rate=None, n_estimators=None, n_jobs=None, gamma=None, min_child_weight=None, max_delta_step=None, subsample=None, sampling_method=None, colsample_bytree=None, colsample_bylevel=None, colsample_bynode=None, reg_alpha=None, reg_lambda=None, scale_pos_weight=None, base_score=None, random_state=None, missing=nan, num_parallel_tree=None, monotone_constraints=None, interaction_constraints=None, importance_type=None, device=None, validate_parameters=None, enable_categorical=False, feature_types=None, max_cat_to_onehot=None, max_cat_threshold=None, multi_strategy=None, eval_metric=None, early_stopping_rounds=None, callbacks=None, **kwargs)

Bases: DaskScikitLearnBase, RegressorMixin

Implementation of the Scikit-Learn API for XGBoost. See *Using the Scikit-Learn Estimator Interface* for more information.

Parameters

- **n_estimators** *(Optional[int]*) – Number of gradient boosted trees. Equivalent to number of boosting rounds.

- **max_depth** *(Optional[int]*) – Maximum tree depth for base learners.

- **max_leaves** *(Optional[int]*) – Maximum number of leaves; 0 indicates no limit.

- **max_bin** *(Optional[int]*) – If using histogram-based algorithm, maximum number of bins per feature

- **grow_policy** *(Optional[str]*) – Tree growing policy.
  - depthwise: Favors splitting at nodes closest to the node,
  - lossguide: Favors splitting at nodes with highest loss change.

- **learning_rate** *(Optional[float]*) – Boosting learning rate (xgb’s “eta”)

- **verbosity** *(Optional[int]*) – The degree of verbosity. Valid values are 0 (silent) - 3 (debug).

- **objective** *(Union[str, xgboost.sklearn._SklObjWProto, Callable[[Any, Any], Tuple[numpy.ndarray, numpy.ndarray]], NoneType]*) – Specify the learning task and the corresponding learning objective or a custom objective function to be used.
For custom objective, see *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information, along with the end note for function signatures.

- **booster** *(Optional[str]*) – Specify which booster to use: gbtree, gblinear or dart.
- **tree_method** *(Optional[str]*) – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available. It’s recommended to study this option from the parameters document *tree method*
- **n_jobs** *(Optional[int]*) – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.
- **gamma** *(Optional[float]*) – *(min_split_loss)* Minimum loss reduction required to make a further partition on a leaf node of the tree.
- **min_child_weight** *(Optional[float]*) – Minimum sum of instance weight(hessian) needed in a child.
- **max_delta_step** *(Optional[float]*) – Maximum delta step we allow each tree’s weight estimation to be.
- **subsample** *(Optional[float]*) – Subsample ratio of the training instance.
- **sampling_method** *(Optional[str]*) – Sampling method. Used only by the GPU version of hist tree method.
  - **uniform**: Select random training instances uniformly.
  - **gradient_based**: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)
- **colsample_bytree** *(Optional[float]*) – Subsample ratio of columns when constructing each tree.
- **colsample_bylevel** *(Optional[float]*) – Subsample ratio of columns for each level.
- **colsample_bynode** *(Optional[float]*) – Subsample ratio of columns for each split.
- **reg_alpha** *(Optional[float]*) – L1 regularization term on weights (xgb’s alpha).
- **reg_lambda** *(Optional[float]*) – L2 regularization term on weights (xgb’s lambda).
- **scale_pos_weight** *(Optional[float]*) – Balancing of positive and negative weights.
- **base_score** *(Optional[float]*) – The initial prediction score of all instances, global bias.
- **random_state** *(Union[numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType]*) – Random number seed.

**Note**

Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.

- **missing** *(float)* – Value in the data which needs to be present as a missing value. Default to *numpy.nan*.
- **num_parallel_tree** *(Optional[int]*) – Used for boosting random forest.
- **monotone_constraints** *(Union[Dict[str, int], str, NoneType]*) – Constraint of variable monotonicity. See *tutorial* for more information.
• interaction_constraints \((\text{Union}[\text{str}, \text{List}[\text{Tuple}[\text{str}]], \text{NoneType}])\) – Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nested list, e.g. \([[[0, 1], [2, 3, 4]]\), where each inner list is a group of indices of features that are allowed to interact with each other. See tutorial for more information.

• importance_type \((\text{Optional}[\text{str}])\) – The feature importance type for the feature_importances_ property:
  – For tree model, it’s either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  – For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

• device \((\text{Optional}[\text{str}])\) – Added in version 2.0.0.
  Device ordinal, available options are \(\text{cpu}\), \(\text{cuda}\), and \(\text{gpu}\).

• validate_parameters \((\text{Optional}[\text{bool}])\) – Give warnings for unknown parameter.

• enable_categorical \((\text{bool})\) – See the same parameter of DMatrix for details.

• feature_types \((\text{Optional}[\text{Sequence}[\text{str}])\) – Added in version 1.7.0.
  Used for specifying feature types without constructing a dataframe. See DMatrix for details.

• max_cat_to_onehot \((\text{Optional}[\text{int}])\) – Added in version 1.6.0.

  ![Note]

  This parameter is experimental

  A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, enable_categorical needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

• max_cat_threshold \((\text{Optional}[\text{int}])\) – Added in version 1.7.0.

  ![Note]

  This parameter is experimental

  Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, enable_categorical needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

• multi_strategy \((\text{Optional}[\text{str}])\) – Added in version 2.0.0.

  ![Note]

  This parameter is working-in-progress.

  The strategy used for training multi-target models, including multi-target regression and multi-class classification. See Multiple Outputs for more information.
- **one_output_per_tree**: One model for each target.
- **multi_output_tree**: Use multi-target trees.

**eval_metric** (*Union[str, List[str], Callable, NoneType]*) – Added in version 1.6.0.

Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in `sklearn.metrics`, or any other user defined metric that looks like `sklearn.metrics`.

If custom objective is also provided, then custom metric should implement the corresponding reverse link function.

Unlike the `scoring` parameter commonly used in scikit-learn, when a callable object is provided, it’s assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

For advanced usage on Early stopping like directly choosing to maximize instead of minimize, see `xgboost.callback.EarlyStopping`.

See *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information.

```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

**early_stopping_rounds** (*Optional[int]*) – Added in version 1.6.0.

- Activates early stopping. Validation metric needs to improve at least once in every **early_stopping_rounds** round(s) to continue training. Requires at least one item in `eval_set` in `fit()`.

- If early stopping occurs, the model will have two additional attributes: `best_score` and `best_iteration`. These are used by the `predict()` and `apply()` methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the `iteration_range` in these inference methods. In addition, other utilities like model plotting can also use the entire model.

- If you prefer to discard the trees after `best_iteration`, consider using the callback function `xgboost.callback.EarlyStopping`.

- If there’s more than one metric in `eval_set`, the last entry will be used for early stopping. If there’s more than one metric in `eval_metric`, the last metric will be used for early stopping.

**callbacks** (*Optional[List[xgboost.callback.TrainingCallback]]*) – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using `Callback API`.

**Note**
States in callback are not preserved during training, which means callback objects cannot be reused for multiple training sessions without reinitialization or deepcopy.

```python
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    reg = xgboost.XGBRegressor(**params, callbacks=callbacks)
    reg.fit(X, y)
```

- **kwargs (Optional[Any]) – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found here. Attempting to set a parameter via the constructor args and **kwargs dict simultaneously will result in a TypeError.

**Note**

**kwargs unsupported by scikit-learn

**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed via this argument will interact properly with scikit-learn.

**apply**(*X*, *iteration_range=None*)

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then `best_iteration` is used automatically.

**Parameters**

- **X** (*array_like*, *shape*=[*n_samples*, *n_features]*) – Input features matrix.
- **iteration_range** (*Tuple[int | integer, int | integer] | None*) – See **predict()**.

**Returns**

- **X_leaves** – For each datapoint x in X and for each tree, return the index of the leaf x ends up in. Leaves are numbered within [0; 2**(self.max_depth+1))], possibly with gaps in the numbering.

**Return type**

array_like, shape=[*n_samples*, *n_trees*]

**property best_iteration**: int

The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is the first round, then best_iteration is 0.

**property best_score**: float

The best score obtained by early stopping.

**property client**: distributed.Client

The dask client used in this model. The `Client` object cannot be serialized for transmission, so if task is launched from a worker instead of directly from the client process, this attribute needs to be set at that worker.

**property coef_**: ndarray

Coefficients property
Coefﬁcients are deﬁned only for linear learners

Coefficients are only deﬁned when the linear model is chosen as base learner (booster=gblinear). It is not deﬁned for other base learner types, such as tree learners (booster=gbtree).

Returns

coef_

Return type

array of shape [n_features] or [n_classes, n_features]

evals_result()

Return the evaluation results.

If eval_set is passed to the fit() function, you can call evals_result() to get evaluation results for all passed eval_sets. When eval_metric is also passed to the fit() function, the evals_result will contain the eval_metrics passed to the fit() function.

The returned evaluation result is a dictionary:

```python
{'validation_0': {'logloss': ['0.604835', '0.531479']},
 'validation_1': {'logloss': ['0.41965', '0.17686']}}
```

Return type

evals_result

property feature_importances_: ndarray

Feature importances property, return depends on importance_type parameter. When model trained with multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “average” is defined based on the importance type. For instance, if the importance type is “total_gain”, then the score is sum of loss change for each split from all trees.

Returns

• feature_importances_ (array of shape [n_features] except for multi-class)
• linear model, which returns an array with shape (n_features, n_classes)

property feature_names_in_: ndarray

Names of features seen during fit(). Defined only when X has feature names that are all strings.

fit(X, y, *, sample_weight=None, base_margin=None, eval_set=None, verbose=True, xgb_model=None, sample_weight_eval_set=None, base_margin_eval_set=None, feature_weights=None)

Fit gradient boosting model.

Note that calling fit() multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass xgb_model argument.

Parameters

• X (da.Array | dd.DataFrame) – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.

When the tree_method is set to hist, internally, the QuantileDMatrix will be used instead of the DMatrix for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a
numpy array on CPU but cuda is used for training, then the data is first processed on CPU then transferred to GPU.

- **sample_weight** *(da.Array | dd.DataFrame | dd.Series | None)* – instance weights
- **base_margin** *(da.Array | dd.DataFrame | dd.Series | None)* – Global bias for each instance. See *Intercept* for details.
- **eval_set** *(Sequence[Tuple[da.Array | dd.DataFrame | dd.Series, da.Array | dd.DataFrame | dd.Series] | None)* – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.
- **verbose** *(int | bool)* – If verbose is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If verbose is an integer, the evaluation metric is printed at each verbose boosting stage. The last boosting stage / the boosting stage found by using *early_stopping_rounds* is also printed.
- **xgb_model** *(Booster | XGBModel | None)* – file name of stored XGBoost model or ‘Booster’ instance XGBoost model to be loaded before training (allows training continuation).
- **sample_weight_eval_set** *(Sequence[da.Array | dd.DataFrame | dd.Series] | None)* – A list of the form [L_1, L_2, ..., L_n], where each L_i is an array like object storing instance weights for the i-th validation set.
- **base_margin_eval_set** *(Sequence[da.Array | dd.DataFrame | dd.Series] | None)* – A list of the form [M_1, M_2, ..., M_n], where each M_i is an array like object storing base margin for the i-th validation set.
- **feature_weights** *(da.Array | dd.DataFrame | dd.Series | None)* – Weight for each feature, defines the probability of each feature being selected when colsample is being used. All values must be greater than 0, otherwise a *ValueError* is thrown.

**Return type**

*DaskXGBRegressor*

**get_booster()**

Get the underlying xgboost Booster of this model.

This will raise an exception when fit was not called

**Returns**

booster

**Return type**

a xgboost booster of underlying model

**get_metadata_routing()**

Get metadata routing of this object.

Please check *User Guide* on how the routing mechanism works.

**Returns**

routing – A *MetadataRequest* encapsulating routing information.

**Return type**

MetadataRequest
get_num_boosting_rounds()  
Gets the number of xgboost boosting rounds.

    Return type
    int
get_params(deep=True)  
Get parameters.

    Parameters
    deep (bool)
    
    Return type
    Dict[str, Any]
get_xgb_params()  
Get xgboost specific parameters.

    Return type
    Dict[str, Any]

property intercept_: ndarray  
Intercept (bias) property

    For tree-based model, the returned value is the base_score.

    Returns
    intercept_
    
    Return type
    array of shape (1,) or [n_classes]
load_model(fname)  
Load the model from a file or a bytearray.

    The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

    model.load_model("model.json")
    # or
    model.load_model("model.ubj")

    Parameters
    fname (str | bytearray | PathLike) – Input file name or memory buffer(see also save_raw)
    
    Return type
    None

property n_features_in_: int  
Number of features seen during fit().

predict(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)  
Predict with X. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.
Note

This function is only thread safe for `gbtree` and `dart`.

Parameters

- **output_margin** *(bool)* – Whether to output the raw untransformed margin value.
- **validate_features** *(bool)* – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
- **base_margin** *(da.Array | dd.DataFrame | dd.Series | None)* – Global bias for each instance. See *Intercept* for details.
- **iteration_range** *(Tuple[int | integer, int | integer] | None)* – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying `iteration_range=(10, 20)`, then only the forests built during [10, 20) (half open set) rounds are used in this prediction.
  
  Added in version 1.4.0.

Return type

`prediction`

**save_model**(fname)

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See *Model IO* for more info.

```python
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

Parameters

- **fname** *(str | PathLike)* – Output file name

Return type

None

**score**(X, y, sample_weight=None)

Return the coefficient of determination of the prediction.

The coefficient of determination $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $(y_{\text{true}} - y_{\text{pred}})^2$.sum() and $v$ is the total sum of squares $(y_{\text{true}} - y_{\text{true.mean}})^2$.sum(). The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** *(array-like of shape (n_samples, n_features))* – Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
• \( y \) (array-like of shape (n_samples,) or (n_samples, n_outputs)) – True values for \( X \).
• sample_weight (array-like of shape (n_samples,), default=None) – Sample weights.

Returns
score – \( R^2 \) of self.predict(\( X \)) w.r.t. \( y \).

Return type
float

Notes
The \( R^2 \) score used when calling score on a regressor uses multioutput='uniform_average' from version 0.23 to keep consistent with default value of r2_score(). This influences the score method of all the multioutput regressors (except for MultiOutputRegressor).

set_fit_request(*, base_margin='UNCHANGED', base_margin_eval_set='UNCHANGED',
 eval_set='UNCHANGED', feature_weights='UNCHANGED',
 sample_weight='UNCHANGED', sample_weight_eval_set='UNCHANGED',
 verbose='UNCHANGED', xgb_model='UNCHANGED')

Request metadata passed to the fit method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:
• True: metadata is requested, and passed to fit if provided. The request is ignored if metadata is not provided.
• False: metadata is not requested and the meta-estimator will not pass it to fit.
• None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
• str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

Note
This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters
• base_margin (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in fit.
• base_margin_eval_set (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin_eval_set parameter in fit.
• **eval_set**  
  *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for eval_set parameter in fit.

• **feature_weights**  
  *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for feature_weights parameter in fit.

• **sample_weight**  
  *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight parameter in fit.

• **sample_weight_eval_set**  
  *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight_eval_set parameter in fit.

• **verbose**  
  *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for verbose parameter in fit.

• **xgb_model**  
  *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for xgb_model parameter in fit.

• **self** *(DaskXGBRegressor)*

**Returns**

`self` – The updated object.

**Return type**

`object`

**set_params(**params**)**

Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

**Return type**

`self`

**Parameters**

`params` *(Any)*

**set_predict_request(***, base_margin='UNCHANGED$', iteration_range='UNCHANGED$', output_margin='UNCHANGED$', validate_features='UNCHANGED$'***)

Request metadata passed to the predict method.

Note that this method is only relevant if `enable_metadata_routing=True` (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• **True**: metadata is requested, and passed to predict if provided. The request is ignored if metadata is not provided.

• **False**: metadata is not requested and the meta-estimator will not pass it to predict.

• **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.

• **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.
The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a **Pipeline**. Otherwise it has no effect.

**Parameters**

- **base_margin** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* — Metadata routing for `base_margin` parameter in `predict`.

- **iteration_range** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* — Metadata routing for `iteration_range` parameter in `predict`.

- **output_margin** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* — Metadata routing for `output_margin` parameter in `predict`.

- **validate_features** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* — Metadata routing for `validate_features` parameter in `predict`.

- **self** *(DaskXGBRegressor)*

**Returns**

- **self** — The updated object.

**Return type**

- **object**

**set_score_request**(*, sample_weight='UNCHANGED')

Request metadata passed to the `score` method.

Note that this method is only relevant if `enable_metadata_routing=True` (see `sklearn.set_config()`). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to `score` if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to `score`.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.
Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

- `sample_weight` *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight parameter in score.

- `self` *(DaskXGBRegressor)*

Returns

- `self` – The updated object.

Return type

- `object`

class xgboost.dask.DaskXGBRanker(*, objective='rank:pairwise', **kwargs)

Bases: DaskScikitLearnBase, XGBRankerMixIn

Implementation of the Scikit-Learn API for XGBoost Ranking.

Added in version 1.4.0.

See Using the Scikit-Learn Estimator Interface for more information.

Parameters

- `n_estimators` *(Optional[int])* – Number of gradient boosted trees. Equivalent to number of boosting rounds.

- `max_depth` *(Optional[int])* – Maximum tree depth for base learners.

- `max_leaves` *(Optional[int])* – Maximum number of leaves; 0 indicates no limit.

- `max_bin` *(Optional[int])* – If using histogram-based algorithm, maximum number of bins per feature

- `grow_policy` *(Optional[str])* – Tree growing policy.
  - depthwise: Favors splitting at nodes closest to the node,
  - lossguide: Favors splitting at nodes with highest loss change.

- `learning_rate` *(Optional[float])* – Boosting learning rate (xgb’s “eta”)

- `verbosity` *(Optional[int])* – The degree of verbosity. Valid values are 0 (silent) - 3 (debug).

- `objective` *(Union[str, xgboost.sklearn._Sk1ObjWProto, Callable[[Any, Any], Tuple[numpy.ndarray, numpy.ndarray]], NoneType])* – Specify the learning task and the corresponding learning objective or a custom objective function to be used.

  For custom objective, see Custom Objective and Evaluation Metric and Custom objective and metric for more information, along with the end note for function signatures.

- `booster` *(Optional[str])* – Specify which booster to use: gbtree, gblinear or dart.
• **tree_method** *(Optional [str])* – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available. It’s recommended to study this option from the parameters document *tree method*

• **n_jobs** *(Optional [int])* – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.

• **gamma** *(Optional [float])* – (min_split_loss) Minimum loss reduction required to make a further partition on a leaf node of the tree.

• **min_child_weight** *(Optional [float])* – Minimum sum of instance weight(hessian) needed in a child.

• **max_delta_step** *(Optional [float])* – Maximum delta step we allow each tree’s weight estimation to be.

• **subsample** *(Optional [float])* – Subsample ratio of the training instance.

• **sampling_method** *(Optional [str])* – Sampling method. Used only by the GPU version of hist tree method.
  - uniform: Select random training instances uniformly.
  - gradient_based: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)

• **colsample_bytree** *(Optional [float])* – Subsample ratio of columns when constructing each tree.

• **colsample_bylevel** *(Optional [float])* – Subsample ratio of columns for each level.

• **colsample_bynode** *(Optional [float])* – Subsample ratio of columns for each split.

• **reg_alpha** *(Optional [float])* – L1 regularization term on weights (xgb’s alpha).

• **reg_lambda** *(Optional [float])* – L2 regularization term on weights (xgb’s lambda).

• **scale_pos_weight** *(Optional [float])* – Balancing of positive and negative weights.

• **base_score** *(Optional [float])* – The initial prediction score of all instances, global bias.

• **random_state** *(Union [numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType])* – Random number seed.

---

**Note**

Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.

• **missing** *(float)* – Value in the data which needs to be present as a missing value. Default to `numpy.nan`.

• **num_parallel_tree** *(Optional [int])* – Used for boosting random forest.

• **monotone_constraints** *(Union [Dict [str, int], str, NoneType])* – Constraint of variable monotonicity. See tutorial for more information.

• **interaction_constraints** *(Union [str, List [Tuple [str]]], NoneType)* – Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nested list, e.g. `[[0, 1], [2, 3, 4]]`, where each inner list is a group of
indices of features that are allowed to interact with each other. See tutorial for more information

• **importance_type** *(Optional[str]*) – The feature importance type for the feature_importances_ property:
  - For tree model, it’s either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  - For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

• **device** *(Optional[str]*) – Added in version 2.0.0.
  Device ordinal, available options are cpu, cuda, and gpu.

• **validate_parameters** *(Optional[bool]*) – Give warnings for unknown parameter.

• **enable_categorical** *(bool)* – See the same parameter of DMatrix for details.

• **feature_types** *(Optional[Sequence[str]*) – Added in version 1.7.0.
  Used for specifying feature types without constructing a dataframe. See DMatrix for details.

• **max_cat_to_onehot** *(Optional[int]*) – Added in version 1.6.0.
  
<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>This parameter is experimental</td>
</tr>
</tbody>
</table>

A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, enable_categorical needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

• **max_cat_threshold** *(Optional[int]*) – Added in version 1.7.0.
  
<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>This parameter is experimental</td>
</tr>
</tbody>
</table>

Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, enable_categorical needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

• **multi_strategy** *(Optional[str]*) – Added in version 2.0.0.
  
<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>This parameter is working-in-progress.</td>
</tr>
</tbody>
</table>

The strategy used for training multi-target models, including multi-target regression and multi-class classification. See Multiple Outputs for more information.

  - one_output_per_tree: One model for each target.
  - multi_output_tree: Use multi-target trees.
• **eval_metric** (*Union*[str, List[str], Callable, NoneType]) – Added in version 1.6.0.

Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in sklearn.metrics, or any other user defined metric that looks like sklearn.metrics.

If custom objective is also provided, then custom metric should implement the corresponding reverse link function.

Unlike the `scoring` parameter commonly used in scikit-learn, when a callable object is provided, it’s assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

For advanced usage on Early stopping like directly choosing to maximize instead of minimize, see `xgboost.callback.EarlyStopping`.

See [Custom Objective and Evaluation Metric](https://xgboost.readthedocs.io/en/latest/python/parameter.html#custom-objective-and-evaluation-metric) and [Custom objective and metric](https://xgboost.readthedocs.io/en/latest/python/parameter.html#custom-objective-and-metric) for more information.

```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

• **early_stopping_rounds** (*Optional*[int]) – Added in version 1.6.0.

  - Activates early stopping. Validation metric needs to improve at least once in every `early_stopping_rounds` round(s) to continue training. Requires at least one item in `eval_set` in `fit()`.

  - If early stopping occurs, the model will have two additional attributes: **best_score** and **best_iteration**. These are used by the `predict()` and `apply()` methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the `iteration_range` in these inference methods. In addition, other utilities like model plotting can also use the entire model.

  - If you prefer to discard the trees after `best_iteration`, consider using the callback function `xgboost.callback.EarlyStopping`.

  - If there’s more than one item in `eval_set`, the last entry will be used for early stopping. If there’s more than one metric in `eval_metric`, the last metric will be used for early stopping.

• **callbacks** (*Optional*[List[xgboost.callback.TrainingCallback]]) – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using `Callback API`.

  💡 **Note**

  States in callback are not preserved during training, which means callback objects cannot be reused for multiple training sessions without reinitialization or deepcopy.
for params in parameters_grid:
  # be sure to (re)initialize the callbacks before each run
  callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
  reg = xgb.XGBRegressor(**params, callbacks=callbacks)
  reg.fit(X, y)

• **kwargs (Optional[Any]) – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found here. Attempting to set a parameter via the constructor args and **kwargs dict simultaneously will result in a TypeError.

    Note

**kwargs unsupported by scikit-learn

**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed via this argument will interact properly with scikit-learn.

    Note

For dask implementation, group is not supported, use qid instead.

apply(X, iteration_range=None)

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then best_iteration is used automatically.

Parameters

• X (array_like, shape=[n_samples, n_features]) – Input features matrix.

• iteration_range (Tuple[int | integer, int | integer] | None) – See predict().

Returns

X_leaves – For each datapoint x in X and for each tree, return the index of the leaf x ends up in. Leaves are numbered within [0; 2**(self.max_depth+1)), possibly with gaps in the numbering.

Return type

array_like, shape=[n_samples, n_trees]

property best_iteration: int

The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is the first round, then best_iteration is 0.

property best_score: float

The best score obtained by early stopping.

property client: distributed.Client

The dask client used in this model. The Client object cannot be serialized for transmission, so if task is launched from a worker instead of directly from the client process, this attribute needs to be set at that worker.

property coef_: ndarray

Coefficients property
Note

Coefficients are defined only for linear learners.
Coefficients are only defined when the linear model is chosen as base learner (booster=gblinear). It is not defined for other base learner types, such as tree learners (booster=gbtree).

Returns

coef_

Return type

array of shape [n_features] or [n_classes, n_features]

evals_result()

Return the evaluation results.

If eval_set is passed to the fit() function, you can call evals_result() to get evaluation results for all passed eval_sets. When eval_metric is also passed to the fit() function, the evals_result will contain the eval_metrics passed to the fit() function.

The returned evaluation result is a dictionary:

```
{'validation_0': {'logloss': ['0.604835', '0.531479']},
 'validation_1': {'logloss': ['0.41965', '0.17686']}}
```

Return type

evals_result

property feature_importances_

Feature importances property, return depends on importance_type parameter. When model trained with multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “average” is defined based on the importance type. For instance, if the importance type is “total_gain”, then the score is sum of loss change for each split from all trees.

Returns

- feature_importances_ (array of shape [n_features] except for multi-class)
- linear model, which returns an array with shape (n_features, n_classes)

property feature_names_in_

Names of features seen during fit(). Defined only when X has feature names that are all strings.

```
fit(X, y, *, group=None, qid=None, sample_weight=None, base_margin=None, eval_set=None,
 eval_group=None, eval_qid=None, verbose=False, xgb_model=None, sample_weight_eval_set=None,
 base_margin_eval_set=None, feature_weights=None)
```

Fit gradient boosting ranker

Note that calling fit() multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass xgb_model argument.

Parameters

- X (da.Array | dd.DataFrame) – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.

  When this is a pandas.DataFrame or a cudf.DataFrame, it may contain a special column called qid for specifying the query index. Using a special column is the same as
using the \textit{qid} parameter, except for being compatible with sklearn utility functions like sklearns.model_selection.cross_validation(). The same convention applies to the XGBRanker.score() and XGBRanker.predict().

<table>
<thead>
<tr>
<th>qid</th>
<th>feat_0</th>
<th>feat_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>$x_{00}$</td>
<td>$x_{01}$</td>
</tr>
<tr>
<td>1</td>
<td>$x_{10}$</td>
<td>$x_{11}$</td>
</tr>
<tr>
<td>1</td>
<td>$x_{20}$</td>
<td>$x_{21}$</td>
</tr>
</tbody>
</table>

When the \texttt{tree_method} is set to hist, internally, the QuantileDMatrix will be used instead of the DMatrix for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a numpy array on CPU but cuda is used for training, then the data is first processed on CPU then transferred to GPU.

- \texttt{y} (da.Array | dd.DataFrame | dd.Series) – Labels
- \texttt{group} (da.Array | dd.DataFrame | dd.Series | None) – Size of each query group of training data. Should have as many elements as the query groups in the training data. If this is set to None, then user must provide qid.
- \texttt{qid} (da.Array | dd.DataFrame | dd.Series | None) – Query ID for each training sample. Should have the size of \texttt{n_samples}. If this is set to None, then user must provide group or a special column in \texttt{X}.
- \texttt{sample_weight} (da.Array | dd.DataFrame | dd.Series | None) – Query group weights

\begin{center}
\textbf{Note}
\end{center}

Weights are per-group for ranking tasks

In ranking task, one weight is assigned to each query group/id (not each data point). This is because we only care about the relative ordering of data points within each group, so it doesn’t make sense to assign weights to individual data points.

- \texttt{base_margin} (da.Array | dd.DataFrame | dd.Series | None) – Global bias for each instance. See \texttt{Intercept} for details.
- \texttt{eval_set} (Sequence[Tuple[da.Array | dd.DataFrame | dd.Series, da.Array | dd.DataFrame | dd.Series]] | None) – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.
- \texttt{eval_group} (Sequence[da.Array | dd.DataFrame | dd.Series] | None) – A list in which \texttt{eval_group[i]} is the list containing the sizes of all query groups in the \texttt{i}-th pair in \texttt{eval_set}.
- \texttt{eval_qid} (Sequence[da.Array | dd.DataFrame | dd.Series] | None) – A list in which \texttt{eval_qid[i]} is the array containing query ID of \texttt{i}-th pair in \texttt{eval_set}. The special column convention in \texttt{X} applies to validation datasets as well.
- \texttt{verbose} (int | bool) – If \texttt{verbose} is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If \texttt{verbose} is an integer, the evaluation metric is printed at each \texttt{verbose} boosting stage. The last boosting stage / the boosting stage found by using \texttt{early_stopping_rounds} is also printed.
• **xgb_model** (*Booster / XGBModel / None*) – file name of stored XGBoost model or ‘Booster’ instance XGBoost model to be loaded before training (allows training continuation).

• **sample_weight_eval_set** (*Sequence[da.Array | dd.DataFrame | dd.Series] / None*) – A list of the form \([L_1, L_2, \ldots, L_n]\), where each \(L_i\) is a list of group weights on the \(i\)-th validation set.

### Note
Weights are per-group for ranking tasks

In ranking task, one weight is assigned to each query group (not each data point). This is because we only care about the relative ordering of data points within each group, so it doesn’t make sense to assign weights to individual data points.

• **base_margin_eval_set** (*Sequence[da.Array | dd.DataFrame | dd.Series] / None*) – A list of the form \([M_1, M_2, \ldots, M_n]\), where each \(M_i\) is an array like object storing base margin for the \(i\)-th validation set.

• **feature_weights** (*da.Array | dd.DataFrame | dd.Series / None*) – Weight for each feature, defines the probability of each feature being selected when colsample is being used. All values must be greater than 0, otherwise a \(ValueError\) is thrown.

**Return type**

*DaskXGBRanker*

**get_booster()**

Get the underlying xgboost Booster of this model.

This will raise an exception when fit was not called

**Returns**

booster

**Return type**

a xgboost booster of underlying model

**get_metadata_routing()**

Get metadata routing of this object.

Please check User Guide on how the routing mechanism works.

**Returns**

routing – A **MetadataRequest** encapsulating routing information.

**Return type**

**get_num_boosting_rounds()**

Gets the number of xgboost boosting rounds.

**Return type**

int

**get_params** (*deep=True*)

Get parameters.

**Parameters**

deep (bool)
Return type

    Dict[str, Any]

get_xgb_params()
Get xgboost specific parameters.

    Return type
    Dict[str, Any]

property intercept_:
Intercept (bias) property
For tree-based model, the returned value is the \textit{base_score}.

    Returns
    intercept_

    Return type
    array of shape (1,) or [n_classes]

load_model(fname)
Load the model from a file or a bytestream.

    Parameters
    - \textit{fname} (str | bytearray | PathLike) – Input file name or memory buffer (see also save_raw)

    Return type
    None

property n_features_in_:
Number of features seen during \textit{fit}().

predict(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)
Predict with \textit{X}. If the model is trained with early stopping, then \textit{best_iteration} is used automatically. The estimator uses \textit{inplace_predict} by default and falls back to using \textit{DMatrix} if devices between the data and the estimator don’t match.

Note
This function is only thread safe for \textit{gbtree} and \textit{dart}.

Parameters

- \textit{output_margin} (bool) – Whether to output the raw untransformed margin value.
- \textit{validate_features} (bool) – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
• **base_margin** (*da.Array | dd.DataFrame | dd.Series | None*) – Global bias for each instance. See *Intercept* for details.

• **iteration_range** (*Tuple[int | integer, int | integer] | None*) – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying iteration_range=(10, 20), then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

  Added in version 1.4.0.

**Return type**
- prediction

### save_model(*fname*)

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See *Model IO* for more info.

```python
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

**Parameters**
- **fname** (*str | PathLike*) – Output file name

**Return type**
- None

### set_fit_request(*, base_margin='UNCHANGED', base_margin_eval_set='UNCHANGED',
  eval_group='UNCHANGED', eval_qid='UNCHANGED',
  eval_set='UNCHANGED', feature_weights='UNCHANGED',
  group='UNCHANGED', qid='UNCHANGED', sample_weight='UNCHANGED',
  sample_weight_eval_set='UNCHANGED', verbose='UNCHANGED',
  xgb_model='UNCHANGED')

Request metadata passed to the `fit` method.

Note that this method is only relevant if *enable_metadata_routing=True* (see *sklearn.set_config()).* Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to `fit` if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to `fit`.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (*sklearn.utils.metadata_routing.UNCHANGED*) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.
Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

- **base_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in fit.

- **base_margin_eval_set** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin_eval_set parameter in fit.

- **eval_group** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for eval_group parameter in fit.

- **eval_qid** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for eval_qid parameter in fit.

- **eval_set** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for eval_set parameter in fit.

- **feature_weights** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for feature_weights parameter in fit.

- **group** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for group parameter in fit.

- **qid** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for qid parameter in fit.

- **sample_weight** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight parameter in fit.

- **sample_weight_eval_set** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight_eval_set parameter in fit.

- **verbose** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for verbose parameter in fit.

- **xgb_model** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for xgb_model parameter in fit.

- **self** (DaskXGBRanker)

Returns

- **self** – The updated object.

Return type

- object
**set_params(**params)

Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

**Return type**

self

**Parameters**

params (Any)

**set_predict_request(***, *, base_margin='UNCHANGED', iteration_range='UNCHANGED', output_margin='UNCHANGED', validate_features='UNCHANGED')

Request metadata passed to the predict method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to predict if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to predict.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

**Parameters**

- **base_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict.
- **iteration_range** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict.
- **output_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for output_margin parameter in predict.
- **validate_features** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict.
- **self** (DaskXGBRanker)
Returns
self – The updated object.

Return type
object

class xgboost.dask.DaskXGBRFRegressor(*, learning_rate=1, subsample=0.8, colsample_bynode=0.8, reg_lambda=1e-05, **kwargs)

Bases: DaskXGBRegressor

Implementation of the Scikit-Learn API for XGBoost Random Forest Regressor.

Added in version 1.4.0.

See Using the Scikit-Learn Estimator Interface for more information.

Parameters

• n_estimators (int) – Number of trees in random forest to fit.
• max_depth (Optional[int]) – Maximum tree depth for base learners.
• max_leaves (Optional[int]) – Maximum number of leaves; 0 indicates no limit.
• max_bin (Optional[int]) – If using histogram-based algorithm, maximum number of bins per feature
• grow_policy (Optional[str]) – Tree growing policy.
  – depthwise: Favors splitting at nodes closest to the node,
  – lossguide: Favors splitting at nodes with highest loss change.
• learning_rate (Optional[float]) – Boosting learning rate (xgb’s “eta”)
• verbosity (Optional[int]) – The degree of verbosity. Valid values are 0 (silent) - 3 (debug).
• objective (Union[str, xgboost.sklearnsklearn._SklObjWProto, Callable[[Any, Any], Tuple[numpy.ndarray, numpy.ndarray]], NoneType]) – Specify the learning task and the corresponding learning objective or a custom objective function to be used.

For custom objective, see Custom Objective and Evaluation Metric and Custom objective and metric for more information, along with the end note for function signatures.
• booster (Optional[str]) – Specify which booster to use: gbtree, gblinear or dart.
• tree_method (Optional[str]) – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available. It’s recommended to study this option from the parameters document tree method
• n_jobs (Optional[int]) – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.
• gamma (Optional[float]) – (min_split_loss) Minimum loss reduction required to make a further partition on a leaf node of the tree.
• min_child_weight (Optional[float]) – Minimum sum of instance weight(hessian) needed in a child.
• max_delta_step (Optional[float]) – Maximum delta step we allow each tree’s weight estimation to be.
• **subsample** *(Optional [float])* – Subsample ratio of the training instance.

• **sampling_method** *(Optional [str])* – Sampling method. Used only by the GPU version of hist tree method.
  – uniform: Select random training instances uniformly.
  – gradient_based: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)

• **colsample_bytree** *(Optional [float])* – Subsample ratio of columns when constructing each tree.

• **colsample_bylevel** *(Optional [float])* – Subsample ratio of columns for each level.

• **colsample_bynode** *(Optional [float])* – Subsample ratio of columns for each split.

• **reg_alpha** *(Optional [float])* – L1 regularization term on weights (xgb’s alpha).

• **reg_lambda** *(Optional [float])* – L2 regularization term on weights (xgb’s lambda).

• **scale_pos_weight** *(Optional [float])* – Balancing of positive and negative weights.

• **base_score** *(Optional [float])* – The initial prediction score of all instances, global bias.

• **random_state** *(Union [numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType])* – Random number seed.

  **Note**

  Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.

• **missing** *(float)* – Value in the data which needs to be present as a missing value. Default to numpy.nan.

• **num_parallel_tree** *(Optional [int])* – Used for boosting random forest.

• **monotone_constraints** *(Union [Dict [str, int], str, NoneType])* – Constraint of variable monotonicity. See tutorial for more information.

• **interaction_constraints** *(Union [str, List [Tuple [str]]], NoneType)* – Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nested list, e.g. [[[0, 1], [2, 3, 4]], where each inner list is a group of indices of features that are allowed to interact with each other. See tutorial for more information.

• **importance_type** *(Optional [str])* – The feature importance type for the feature_importances_ property:
  – For tree model, it’s either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  – For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

• **device** *(Optional [str])* – Added in version 2.0.0.
  Device ordinal, available options are cpu, cuda, and gpu.

• **validate_parameters** *(Optional [bool])* – Give warnings for unknown parameter.

• **enable_categorical** *(bool)* – See the same parameter of DMatrix for details.
• **feature_types** *(Optional[Sequence[str]])* – Added in version 1.7.0.

Used for specifying feature types without constructing a dataframe. See DMatrix for details.

• **max_cat_to_onehot** *(Optional[int])* – Added in version 1.6.0.

  **Note**
  This parameter is experimental

A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, `enable_categorical` needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

• **max_cat_threshold** *(Optional[int])* – Added in version 1.7.0.

  **Note**
  This parameter is experimental

Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, `enable_categorical` needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

• **multi_strategy** *(Optional[str])* – Added in version 2.0.0.

  **Note**
  This parameter is working-in-progress.

The strategy used for training multi-target models, including multi-target regression and multi-class classification. See Multiple Outputs for more information.

  – one_output_per_tree: One model for each target.

• **eval_metric** *(Union[str, List[str], Callable, NoneType])* – Added in version 1.6.0.

Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in sklearn.metrics, or any other user defined metric that looks like sklearn.metrics.

If custom objective is also provided, then custom metric should implement the corresponding reverse link function.

Unlike the `scoring` parameter commonly used in scikit-learn, when a callable object is provided, it’s assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

For advanced usage on Early stopping like directly choosing to maximize instead of minimize, see `xgboost.callback.EarlyStopping`.
See Custom Objective and Evaluation Metric and Custom objective and metric for more information.

```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

- **early_stopping_rounds** *(Optional[int])* – Added in version 1.6.0.
  - Activates early stopping. Validation metric needs to improve at least once in every early_stopping_rounds round(s) to continue training. Requires at least one item in eval_set in `fit()`.
  - If early stopping occurs, the model will have two additional attributes: `best_score` and `best_iteration`. These are used by the `predict()` and `apply()` methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the `iteration_range` in these inference methods. In addition, other utilities like model plotting can also use the entire model.
  - If you prefer to discard the trees after `best_iteration`, consider using the callback function `xgboost.callback.EarlyStopping`.
  - If there’s more than one item in `eval_set`, the last entry will be used for early stopping. If there’s more than one metric in `eval_metric`, the last metric will be used for early stopping.

- **callbacks** *(Optional[List[xgboost.callback.TrainingCallback]])* – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using Callback API.

**Note**

States in callback are not preserved during training, which means callback objects cannot be reused for multiple training sessions without reinitialization or deepcopy.

```python
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    reg = xgboost.XGBRegressor(**params, callbacks=callbacks)
    reg.fit(X, y)
```

- **kwargs** *(Optional[Any])* – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found here. Attempting to set a parameter via the constructor args and **kwargs dict simultaneously will result in a TypeError.

**Note**

**kwargs unsupported by scikit-learn
**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed via this argument will interact properly with scikit-learn.

## Note

A custom objective function can be provided for the objective parameter. In this case, it should have the signature `objective(y_true, y_pred) -> [grad, hess]` or `objective(y_true, y_pred, *, sample_weight) -> [grad, hess]`:

- **y_true**: `array_like` of shape `[n_samples]`
  The target values
- **y_pred**: `array_like` of shape `[n_samples]`
  The predicted values
- **sample_weight**:
  Optional sample weights.
- **grad**: `array_like` of shape `[n_samples]`
  The value of the gradient for each sample point.
- **hess**: `array_like` of shape `[n_samples]`
  The value of the second derivative for each sample point

### apply(X, iteration_range=None)

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then `best_iteration` is used automatically.

**Parameters**

- **X** (`array_like`, shape=[`n_samples`, `n_features`]) – Input features matrix.
- **iteration_range** (`Tuple[int | integer, int | integer] | None`) – See `predict()`.

**Returns**

- **X_leaves** – For each datapoint x in X and for each tree, return the index of the leaf x ends up in. Leaves are numbered within `[0; 2**(self.max_depth+1))`, possibly with gaps in the numbering.

**Return type**

`array_like`, shape=[`n_samples`, `n_trees`]

**property best_iteration**: `int`

The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is the first round, then best_iteration is 0.

**property best_score**: `float`

The best score obtained by early stopping.

**property client**: `distributed.Client`

The dask client used in this model. The *Client* object can not be serialized for transmission, so if task is launched from a worker instead of directly from the client process, this attribute needs to be set at that worker.
property coef_: ndarray
Coefficients property

Note
Coefficients are defined only for linear learners
Coefficients are only defined when the linear model is chosen as base learner (booster=gblinear). It is not defined for other base learner types, such as tree learners (booster=gbtree).

Returns
t
Return type
t

property evals_result():
Return the evaluation results.
If eval_set is passed to the fit() function, you can call evals_result() to get evaluation results for all passed eval_sets. When eval_metric is also passed to the fit() function, the evals_result will contain the eval_metrics passed to the fit() function.
The returned evaluation result is a dictionary:

```python
{ 'validation_0': { 'logloss': ['0.604835', '0.531479'] },
 'validation_1': { 'logloss': ['0.41965', '0.17686'] }}
```

Return type
evals_result

property feature_importances_: ndarray
Feature importances property, return depends on importance_type parameter. When model trained with multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “average” is defined based on the importance type. For instance, if the importance type is “total_gain”, then the score is sum of loss change for each split from all trees.

Returns

- feature_importances_ (array of shape [n_features] except for multi-class)
- linear model, which returns an array with shape (n_features, n_classes)

property feature_names_in_: ndarray
Names of features seen during fit(). Defined only when X has feature names that are all strings.

fit(X, y, *, sample_weight=None, base_margin=None, eval_set=None, verbose=True, xgb_model=None, sample_weight_eval_set=None, base_margin_eval_set=None, feature_weights=None)
Fit gradient boosting model.
Note that calling fit() multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass xgb_model argument.

Parameters

- X (da.Array | dd.DataFrame) – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.
When the `tree_method` is set to `hist`, internally, the `QuantileDMatrix` will be used instead of the `DMatrix` for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a numpy array on CPU but cuda is used for training, then the data is first processed on CPU then transferred to GPU.

- **y** (`da.Array` | `dd.DataFrame` | `dd.Series`) – Labels
- **sample_weight** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`) – instance weights
- **eval_set** (`Sequence[ Tuple[da.Array | dd.DataFrame | dd.Series, da. Array | dd.DataFrame | dd.Series]] | None`) – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.
- **verbose** (`int` | `bool`) – If `verbose` is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If `verbose` is an integer, the evaluation metric is printed at each `verbose` boosting stage. The last boosting stage / the boosting stage found by using `early_stopping_rounds` is also printed.
- **xgb_model** (`Booster` | `XGBModel` | `None`) – file name of stored XGBoost model or ‘Booster’ instance XGBoost model to be loaded before training (allows training continuation).
- **sample_weight_eval_set** (`Sequence[da.Array | dd.DataFrame | dd.Series]` | `None`) – A list of the form [L_1, L_2, ..., L_n], where each L_i is an array like object storing instance weights for the i-th validation set.
- **base_margin_eval_set** (`Sequence[da.Array | dd.DataFrame | dd.Series]` | `None`) – A list of the form [M_1, M_2, ..., M_n], where each M_i is an array like object storing base margin for the i-th validation set.
- **feature_weights** (`da.Array` | `dd.DataFrame` | `dd.Series` | `None`) – Weight for each feature. defines the probability of each feature being selected when colsample is being used. All values must be greater than 0, otherwise a `ValueError` is thrown.

**Return type**

*DaskXGBRFRegressor*

**get_booster()**

Get the underlying xgboost Booster of this model.

This will raise an exception when fit was not called

**Returns**

booster

**Return type**

a xgboost booster of underlying model

**get_metadata_routing()**

Get metadata routing of this object.

Please check User Guide on how the routing mechanism works.

**Returns**

routing – A `MetadataRequest` encapsulating routing information.
Return type
MetadataRequest

get_num_boosting_rounds()
Gets the number of xgboost boosting rounds.

Return type
int

get_params(deep=True)
Get parameters.

Parameters
deep (bool)

Return type
Dict[str, Any]

get_xgb_params()
Get xgboost specific parameters.

Return type
Dict[str, Any]

property intercept_: ndarray
Intercept (bias) property
For tree-based model, the returned value is the base_score.

Returns
intercept_

Return type
array of shape (1,) or [n_classes]

load_model(fname)
Load the model from a file or a bytearray.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

```
model.load_model("model.json")
# or
model.load_model("model.ubj")
```

Parameters
fname (str | bytearray | PathLike) – Input file name or memory buffer(see also save_raw)

Return type
None

property n_features_in_: int
Number of features seen during fit().

predict(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)
Predict with X. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.
Note
This function is only thread safe for `gbtree` and `dart`.

Parameters

- **output_margin** *(bool)* – Whether to output the raw untransformed margin value.
- **validate_features** *(bool)* – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
- **base_margin** *(da.Array | dd.DataFrame | dd.Series | None)* – Global bias for each instance. See *Intercept* for details.
- **iteration_range** *(Tuple[int | integer, int | integer] | None)* – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying `iteration_range=(10, 20)`, then only the forests built during [10, 20) (half open set) rounds are used in this prediction.
  
  Added in version 1.4.0.

Return type

- **prediction**

save_model *(fname)*

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See *Model IO* for more info.

```python
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

Parameters

- **fname** *(str | PathLike)* – Output file name

Return type

- **None**

score *(X, y, sample_weight=None)*

Return the coefficient of determination of the prediction.

The coefficient of determination $R^2$ is defined as $(1 - \frac{u}{v})$, where $u$ is the residual sum of squares $((y_{true} - y_{pred})^2).\text{sum()}$ and $v$ is the total sum of squares $((y_{true} - y_{true}.\text{mean()})^2).\text{sum()}$. The best possible score is 1.0 and it can be negative (because the model can be arbitrarily worse). A constant model that always predicts the expected value of $y$, disregarding the input features, would get a $R^2$ score of 0.0.

Parameters

- **X** *(array-like of shape (n_samples, n_features))* – Test samples. For some estimators this may be a precomputed kernel matrix or a list of generic objects instead with shape (n_samples, n_samples_fitted), where n_samples_fitted is the number of samples used in the fitting for the estimator.
• \(y\) (array-like of shape (n_samples,) or (n_samples, n_outputs)) – True values for \(X\).

• \texttt{sample_weight}\ (array-like of shape (n_samples,), default=None) – Sample weights.

Returns

\texttt{score} – \(R^2\) of self.predict(\(X\)) w.r.t. \(y\).

Return type

float

Notes

The \(R^2\) score used when calling score on a regressor uses multioutput=’uniform_average’ from version 0.23 to keep consistent with default value of \texttt{r2_score()}. This influences the score method of all the multioutput regressors (except for \texttt{MultiOutputRegressor}).

\texttt{set_fit_request(*, base_margin=\$UNCHANGED\$, base_margin_eval_set=\$UNCHANGED\$, eval_set=\$UNCHANGED\$, feature_weights=\$UNCHANGED\$, sample_weight=\$UNCHANGED\$, sample_weight_eval_set=\$UNCHANGED\$, verbose=\$UNCHANGED\$, xgb_model=\$UNCHANGED\$)}

Request metadata passed to the fit method.

Note that this method is only relevant if \texttt{enable_metadata_routing=True} (see \texttt{sklearn.set_config()}). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• \texttt{True}: metadata is requested, and passed to \texttt{fit} if provided. The request is ignored if metadata is not provided.

• \texttt{False}: metadata is not requested and the meta-estimator will not pass it to \texttt{fit}.

• \texttt{None}: metadata is not requested, and the meta-estimator will raise an error if the user provides it.

• \texttt{str}: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (\texttt{sklearn.utils.metadata_routing.UNCHANGED}) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a \texttt{Pipeline}. Otherwise it has no effect.

Parameters

• \texttt{base_margin} \quad (\texttt{str}, \texttt{True}, \texttt{False}, or \texttt{None}, \texttt{default=sklearn.utils.metadata_routing.UNCHANGED}) – Metadata routing for \texttt{base_margin} parameter in \texttt{fit}.

• \texttt{base_margin_eval_set} \quad (\texttt{str}, \texttt{True}, \texttt{False}, or \texttt{None}, \texttt{default=sklearn.utils.metadata_routing.UNCHANGED}) – Metadata routing for \texttt{base_margin_eval_set} parameter in \texttt{fit}.
• **eval_set** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for eval_set parameter in fit.

• **feature_weights** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for feature_weights parameter in fit.

• **sample_weight** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight parameter in fit.

• **sample_weight_eval_set** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for sample_weight_eval_set parameter in fit.

• **verbose** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for verbose parameter in fit.

• **xgb_model** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for xgb_model parameter in fit.

• **self** *(DaskXGBRFRegressor)*

**Returns**

self – The updated object.

**Return type**

object

**set_params(**params**)

Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

**Return type**

self

**Parameters**

params *(Any)*

**set_predict_request(****base_margin='UNCHANGED', iteration_range='UNCHANGED', output_margin='UNCHANGED', validate_features='UNCHANGED')****

Request metadata passed to the predict method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• **True**: metadata is requested, and passed to predict if provided. The request is ignored if metadata is not provided.

• **False**: metadata is not requested and the meta-estimator will not pass it to predict.

• **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.

• **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.
The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

Note
This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

- **base_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict.
- **iteration_range** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict.
- **output_margin** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for output_margin parameter in predict.
- **validate_features** (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict.
- **self** (DaskXGBRFRegressor)

Returns

**self** – The updated object.

Return type

**object**

set_score_request(*, sample_weight='UNCHANGED')

Request metadata passed to the score method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to score if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to score.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.
This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g., used inside a `Pipeline`. Otherwise it has no effect.

### Parameters

- **sample_weight** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)*: Metadata routing for `sample_weight` parameter in `score`.
- **self** *(DaskXGBRFRegressor)*

### Returns

**self** – The updated object.

### Return type

**object**

class xgboost.dask.DaskXGBRFClassifier(*, learning_rate=1, subsample=0.8, colsample_bynode=0.8, reg_lambda=1e-05, **kwargs)

Bases: `DaskXGBClassifier`

Implementation of the Scikit-Learn API for XGBoost Random Forest Classifier.

Added in version 1.4.0.

See *Using the Scikit-Learn Estimator Interface* for more information.

### Parameters

- **n_estimators** *(int)*: Number of trees in random forest to fit.
- **max_depth** *(Optional[int])*: Maximum tree depth for base learners.
- **max_leaves** *(Optional[int])*: Maximum number of leaves; 0 indicates no limit.
- **max_bin** *(Optional[int])*: If using histogram-based algorithm, maximum number of bins per feature.
- **grow_policy** *(Optional[str])*: Tree growing policy.
  - depthwise: Favors splitting at nodes closest to the node,
  - lossguide: Favors splitting at nodes with highest loss change.
- **learning_rate** *(Optional[float])*: Boosting learning rate (xgb’s “eta”)
- **verbosity** *(Optional[int])*: The degree of verbosity. Valid values are 0 (silent) - 3 (debug).
- **objective** *(Union[str, xgboost.sklearn._SklObjWProto, Callable[[Any, Any], Tuple[numpy.ndarray, numpy.ndarray]], NoneType])*: Specify the learning task and the corresponding learning objective or a custom objective function to be used.

For custom objective, see *Custom Objective and Evaluation Metric* and *Custom objective and metric* for more information, along with the end note for function signatures.

- **booster** *(Optional[str])*: Specify which booster to use: gbtree, gblinear or dart.
- tree_method (Optional[str]) – Specify which tree method to use. Default to auto. If this parameter is set to default, XGBoost will choose the most conservative option available. It’s recommended to study this option from the parameters document tree method

- n_jobs (Optional[int]) – Number of parallel threads used to run xgboost. When used with other Scikit-Learn algorithms like grid search, you may choose which algorithm to parallelize and balance the threads. Creating thread contention will significantly slow down both algorithms.

- gamma (Optional[float]) – (min_split_loss) Minimum loss reduction required to make a further partition on a leaf node of the tree.

- min_child_weight (Optional[float]) – Minimum sum of instance weight(hessian) needed in a child.

- max_delta_step (Optional[float]) – Maximum delta step we allow each tree’s weight estimation to be.

- subsample (Optional[float]) – Subsample ratio of the training instance.

- sampling_method (Optional[str]) – Sampling method. Used only by the GPU version of hist tree method.
  - uniform: Select random training instances uniformly.
  - gradient_based: Select random training instances with higher probability when the gradient and hessian are larger. (cf. CatBoost)

- colsample_bytree (Optional[float]) – Subsample ratio of columns when constructing each tree.

- colsample_bylevel (Optional[float]) – Subsample ratio of columns for each level.

- colsample_bynode (Optional[float]) – Subsample ratio of columns for each split.

- reg_alpha (Optional[float]) – L1 regularization term on weights (xgb’s alpha).

- reg_lambda (Optional[float]) – L2 regularization term on weights (xgb’s lambda).

- scale_pos_weight (Optional[float]) – Balancing of positive and negative weights.

- base_score (Optional[float]) – The initial prediction score of all instances, global bias.

- random_state (Union[numpy.random.mtrand.RandomState, numpy.random._generator.Generator, int, NoneType]) – Random number seed.

important

Using gblinear booster with shotgun updater is nondeterministic as it uses Hogwild algorithm.

- missing (float) – Value in the data which needs to be present as a missing value. Default to numpy.nan.

- num_parallel_tree (Optional[int]) – Used for boosting random forest.

- monotone_constraints (Union[Dict[str, int], str, NoneType]) – Constraint of variable monotonicity. See tutorial for more information.

- interaction_constraints (Union[str, List[Tuple[str]]], NoneType) – Constraints for interaction representing permitted interactions. The constraints must be specified in the form of a nested list, e.g. [[0, 1], [2, 3, 4]], where each inner list is a group of
indices of features that are allowed to interact with each other. See tutorial for more information

- **importance_type** *(Optional*[str]*) – The feature importance type for the feature_importances_ property:
  - For tree model, it’s either “gain”, “weight”, “cover”, “total_gain” or “total_cover”.
  - For linear model, only “weight” is defined and it’s the normalized coefficients without bias.

- **device** *(Optional*[str]*) – Added in version 2.0.0.
  Device ordinal, available options are `cpu`, `cuda`, and `gpu`.

- **validate_parameters** *(Optional*[bool]*) – Give warnings for unknown parameter.

- **enable_categorical** *(bool)* – See the same parameter of DMatrix for details.

- **feature_types** *(Optional*[Sequence*[str]*)* – Added in version 1.7.0.
  Used for specifying feature types without constructing a dataframe. See DMatrix for details.

- **max_cat_to_onehot** *(Optional*[int]*) – Added in version 1.6.0.

  **Note**
  This parameter is experimental

  A threshold for deciding whether XGBoost should use one-hot encoding based split for categorical data. When number of categories is lesser than the threshold then one-hot encoding is chosen, otherwise the categories will be partitioned into children nodes. Also, enable_categorical needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

- **max_cat_threshold** *(Optional*[int]*) – Added in version 1.7.0.

  **Note**
  This parameter is experimental

  Maximum number of categories considered for each split. Used only by partition-based splits for preventing over-fitting. Also, enable_categorical needs to be set to have categorical feature support. See Categorical Data and Parameters for Categorical Feature for details.

- **multi_strategy** *(Optional*[str]*) – Added in version 2.0.0.

  **Note**
  This parameter is working-in-progress.

  The strategy used for training multi-target models, including multi-target regression and multi-class classification. See Multiple Outputs for more information.

  - one_output_per_tree: One model for each target.
  - multi_output_tree: Use multi-target trees.
• **eval_metric** *(Union[str, List[str], Callable, NoneType])* – Added in version 1.6.0.

Metric used for monitoring the training result and early stopping. It can be a string or list of strings as names of predefined metric in XGBoost (See doc/parameter.rst), one of the metrics in sklearn.metrics, or any other user defined metric that looks like sklearn.metrics.

If custom objective is also provided, then custom metric should implement the corresponding reverse link function.

Unlike the *scoring* parameter commonly used in scikit-learn, when a callable object is provided, it’s assumed to be a cost function and by default XGBoost will minimize the result during early stopping.

For advanced usage on Early stopping like directly choosing to maximize instead of minimize, see xgboost.callback.EarlyStopping.

See Custom Objective and Evaluation Metric and Custom objective and metric for more information.

```python
from sklearn.datasets import load_diabetes
from sklearn.metrics import mean_absolute_error
X, y = load_diabetes(return_X_y=True)
reg = xgb.XGBRegressor(
    tree_method="hist",
    eval_metric=mean_absolute_error,
)
reg.fit(X, y, eval_set=[(X, y)])
```

• **early_stopping_rounds** *(Optional[int])* – Added in version 1.6.0.

  – Activates early stopping. Validation metric needs to improve at least once in every early_stopping_rounds round(s) to continue training. Requires at least one item in eval_set in fit().

  – If early stopping occurs, the model will have two additional attributes: best_score and best_iteration. These are used by the predict() and apply() methods to determine the optimal number of trees during inference. If users want to access the full model (including trees built after early stopping), they can specify the iteration_range in these inference methods. In addition, other utilities like model plotting can also use the entire model.

  – If you prefer to discard the trees after best_iteration, consider using the callback function xgboost.callback.EarlyStopping.

  – If there’s more than one item in eval_set, the last entry will be used for early stopping. If there’s more than one metric in eval_metric, the last metric will be used for early stopping.

• **callbacks** *(Optional[List[xgboost.callback.TrainingCallback]])* – List of callback functions that are applied at end of each iteration. It is possible to use predefined callbacks by using Callback API.

**Note**

States in callback are not preserved during training, which means callback objects cannot be reused for multiple training sessions without reinitialization or deepcopy.
for params in parameters_grid:
    # be sure to (re)initialize the callbacks before each run
    callbacks = [xgb.callback.LearningRateScheduler(custom_rates)]
    reg = xgboost.XGBRegressor(**params, callbacks=callbacks)
    reg.fit(X, y)

• **kwargs (Optional[Any]) – Keyword arguments for XGBoost Booster object. Full documentation of parameters can be found here. Attempting to set a parameter via the constructor args and **kwargs dict simultaneously will result in a TypeError.

  Note

**kwargs unsupported by scikit-learn

**kwargs is unsupported by scikit-learn. We do not guarantee that parameters passed via this argument will interact properly with scikit-learn.

  Note

Custom objective function

A custom objective function can be provided for the objective parameter. In this case, it should have the signature objective(y_true, y_pred) -> [grad, hess] or objective(y_true, y_pred, *, sample_weight) -> [grad, hess]:

  y_true: array_like of shape [n_samples]
  The target values

  y_pred: array_like of shape [n_samples]
  The predicted values

  sample_weight :
      Optional sample weights.

  grad: array_like of shape [n_samples]
  The value of the gradient for each sample point.

  hess: array_like of shape [n_samples]
  The value of the second derivative for each sample point

apply(X, iteration_range=None)

Return the predicted leaf every tree for each sample. If the model is trained with early stopping, then best_iteration is used automatically.

Parameters

• X (array_like, shape=[n_samples, n_features]) – Input features matrix.

• iteration_range (Tuple[int | integer, int | integer] | None) – See predict().

Returns

X_leaves – For each datapoint x in X and for each tree, return the index of the leaf x ends up in. Leaves are numbered within [0; 2**(self.max_depth+1)], possibly with gaps in the numbering.
property best_iteration: int
   The best iteration obtained by early stopping. This attribute is 0-based, for instance if the best iteration is
   the first round, then best_iteration is 0.

property best_score: float
   The best score obtained by early stopping.

property client: distributed.Client
   The dask client used in this model. The Client object cannot be serialized for transmission, so if task is
   launched from a worker instead of directly from the client process, this attribute needs to be set at that
   worker.

property coef_: ndarray
   Coefficients property

   Note
   Coefficients are defined only for linear learners
   Coefficients are only defined when the linear model is chosen as base learner (booster=gblinear). It is
   not defined for other base learner types, such as tree learners (booster=gbtree).

Returns

   coef_

Return type
   array_like, shape=[n_samples, n_trees]

evals_result()
   Return the evaluation results.
   If eval_set is passed to the fit() function, you can call evals_result() to get evaluation results for all
   passed eval_sets. When eval_metric is also passed to the fit() function, the evals_result will contain
   the eval_metrics passed to the fit() function.

   The returned evaluation result is a dictionary:

   ```
   {'validation_0': {'logloss': ['0.604835', '0.531479']},
    'validation_1': {'logloss': ['0.41965', '0.17686']}}
   ```

Return type
   array of shape [n_features] or [n_classes, n_features]

property feature_importances_: ndarray
   Feature importances property, return depends on importance_type parameter. When model trained with
   multi-class/multi-label/multi-target dataset, the feature importance is “averaged” over all targets. The “av-
   erage” is defined based on the importance type. For instance, if the importance type is “total_gain”, then
   the score is sum of loss change for each split from all trees.

Returns

   • feature_importances_ (array of shape [n_features] except for multi-class)
   • linear model, which returns an array with shape (n_features, n_classes)
property feature_names_in_: ndarray

Names of features seen during fit(). Defined only when X has feature names that are all strings.

fit(X, y, *, sample_weight=None, base_margin=None, eval_set=None, verbose=True, xgb_model=None, sample_weight_eval_set=None, base_margin_eval_set=None, feature_weights=None)

Fit gradient boosting model.

Note that calling fit() multiple times will cause the model object to be re-fit from scratch. To resume training from a previous checkpoint, explicitly pass xgb_model argument.

Parameters

- X (da.Array | dd.DataFrame) – Feature matrix. See Supported data structures for various XGBoost functions for a list of supported types.

  When the tree_method is set to hist, internally, the QuantileDMatrix will be used instead of the DMatrix for conserving memory. However, this has performance implications when the device of input data is not matched with algorithm. For instance, if the input is a numpy array on CPU but cuda is used for training, then the data is first processed on CPU then transferred to GPU.

- sample_weight (da.Array | dd.DataFrame | dd.Series | None) – instance weights

- eval_set (Sequence[Tuple[da.Array | dd.DataFrame | dd.Series, da.Array | dd.DataFrame | dd.Series]] | None) – A list of (X, y) tuple pairs to use as validation sets, for which metrics will be computed. Validation metrics will help us track the performance of the model.

- verbose (int | bool) – If verbose is True and an evaluation set is used, the evaluation metric measured on the validation set is printed to stdout at each boosting stage. If verbose is an integer, the evaluation metric is printed at each verbose boosting stage. The last boosting stage / the boosting stage found by using early_stopping_rounds is also printed.

- xgb_model (Booster | XGBModel | None) – file name of stored XGBoost model or ‘Booster’ instance XGBoost model to be loaded before training (allows training continuation).

- sample_weight_eval_set (Sequence[da.Array | dd.DataFrame | dd.Series] | None) – A list of the form [L_1, L_2, ..., L_n], where each L_i is an array like object storing instance weights for the i-th validation set.

- base_margin_eval_set (Sequence[da.Array | dd.DataFrame | dd.Series] | None) – A list of the form [M_1, M_2, ..., M_n], where each M_i is an array like object storing base margin for the i-th validation set.

- feature_weights (da.Array | dd.DataFrame | dd.Series | None) – Weight for each feature, defines the probability of each feature being selected when colsample is being used. All values must be greater than 0, otherwise a ValueError is thrown.

Return type

DaskXGBRFClassifier

get_booster()

Get the underlying xgboost Booster of this model.

This will raise an exception when fit was not called
Returns
booster
Return type
a xgboost booster of underlying model

get_metadata_routing()
Get metadata routing of this object.
Please check User Guide on how the routing mechanism works.

Returns
routing – A MetadataRequest encapsulating routing information.

Return type
MetadataRequest

get_num_boosting_rounds()
Gets the number of xgboost boosting rounds.

Return type
int

get_params(\texttt{deep=True})
Get parameters.

Parameters
\texttt{deep (bool)}

Return type
Dict[\texttt{str, Any}]

get_xgb_params()
Get xgboost specific parameters.

Return type
Dict[\texttt{str, Any}]

\texttt{property intercept_: ndarray}
Intercept (bias) property
For tree-based model, the returned value is the \texttt{base_score}.

Returns
intercept_

Return type
array of shape (1,) or [n_classes]

load_model(\texttt{name})
Load the model from a file or a bytestring.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See Model IO for more info.

```python
model.load_model("model.json")
# or
model.load_model("model.ubj")
```
Parameters

**fname (str | bytearray | PathLike)** – Input file name or memory buffer (see also save_raw)

**Return type**
None

**property n_features_in_: int**
Number of features seen during fit().

**predict(X, output_margin=False, validate_features=True, base_margin=None, iteration_range=None)**
Predict with X. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.

**Note**
This function is only thread safe for gbtree and dart.

Parameters

- **output_margin (bool)** – Whether to output the raw untransformed margin value.
- **validate_features (bool)** – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
- **iteration_range (Tuple[int | integer, int | integer] | None)** – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying iteration_range=(10, 20), then only the forests built during [10, 20) (half open set) rounds are used in this prediction.
  Added in version 1.4.0.

**Return type**
prediction

**predict_proba(X, validate_features=True, base_margin=None, iteration_range=None)**
Predict the probability of each X example being of a given class. If the model is trained with early stopping, then best_iteration is used automatically. The estimator uses inplace_predict by default and falls back to using DMatrix if devices between the data and the estimator don’t match.

**Note**
This function is only thread safe for gbtree and dart.

Parameters

- **validate_features (bool)** – When this is True, validate that the Booster’s and data’s feature_names are identical. Otherwise, it is assumed that the feature_names are the same.
• **base_margin** *(da.Array | dd.DataFrame | dd.Series | None)* – Global bias for each instance. See **Intercept** for details.

• **iteration_range** *(Tuple[int | integer, int | integer] | None)* – Specifies which layer of trees are used in prediction. For example, if a random forest is trained with 100 rounds. Specifying **iteration_range=(10, 20)**, then only the forests built during [10, 20) (half open set) rounds are used in this prediction.

**Returns**

A numpy array of shape array-like of shape (n_samples, n_classes) with the probability of each data example being of a given class.

**Return type**

**prediction**

**save_model**(fname)

Save the model to a file.

The model is saved in an XGBoost internal format which is universal among the various XGBoost interfaces. Auxiliary attributes of the Python Booster object (such as feature_names) are only saved when using JSON or UBJSON (default) format. See **Model IO** for more info.

```python
model.save_model("model.json")
# or
model.save_model("model.ubj")
```

**score**(X, y, sample_weight=None)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

**Parameters**

- **X** *(array-like of shape (n_samples, n_features))* – Test samples.
- **y** *(array-like of shape (n_samples,) or (n_samples, n_outputs))* – True labels for X.
- **sample_weight** *(array-like of shape (n_samples,), default=None)* – Sample weights.

**Returns**

**score** – Mean accuracy of `self.predict(X)` w.r.t. `y`.

**Return type**

**float**

**set_fit_request**(*, base_margin='UNCHANGEDS', base_margin_eval_set='UNCHANGEDS',
eval_set='UNCHANGEDS', feature_weights='UNCHANGEDS',
sample_weight='UNCHANGEDS', sample_weight_eval_set='UNCHANGEDS',
verbose='UNCHANGEDS', xgb_model='UNCHANGEDS')

Request metadata passed to the **fit** method.
Note that this method is only relevant if `enable_metadata_routing=True` (see `sklearn.set_config()`). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

- **True**: metadata is requested, and passed to `fit` if provided. The request is ignored if metadata is not provided.
- **False**: metadata is not requested and the meta-estimator will not pass it to `fit`.
- **None**: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- **str**: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (`sklearn.utils.metadata_routing.UNCHANGED`) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

**Note**

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a `Pipeline`. Otherwise it has no effect.

**Parameters**

- **base_margin** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in `fit`.*
- **base_margin_eval_set** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin_eval_set parameter in `fit`.*
- **eval_set** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for eval_set parameter in `fit`.*
- **feature_weights** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for feature_weights parameter in `fit`.*
- **sample_weight** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight parameter in `fit`.*
- **sample_weight_eval_set** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for sample_weight_eval_set parameter in `fit`.*
- **verbose** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for verbose parameter in `fit`.*
- **xgb_model** *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for xgb_model parameter in `fit`.*
- **self** *(DaskXGBRFClassifier)*
Returns

self – The updated object.

Return type

object

set_params(**params)

Set the parameters of this estimator. Modification of the sklearn method to allow unknown kwargs. This allows using the full range of xgboost parameters that are not defined as member variables in sklearn grid search.

Return type

self

Parameters

params (Any)

set_predict_proba_request(*, base_margin=sklearn.utils.metadata_routing.UNCHANGED, iteration_range=sklearn.utils.metadata_routing.UNCHANGED, validate_features=sklearn.utils.metadata_routing.UNCHANGED)

Request metadata passed to the predict_proba method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• True: metadata is requested, and passed to predict_proba if provided. The request is ignored if metadata is not provided.

• False: metadata is not requested and the meta-estimator will not pass it to predict_proba.

• None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.

• str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

• base_margin (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict_proba.

• iteration_range (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict_proba.

• validate_features (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict_proba.
set_predict_request(*, base_margin='UNCHANGED', iteration_range='UNCHANGED', output_margin='UNCHANGED', validate_features='UNCHANGED')

Request metadata passed to the predict method.

Note that this method is only relevant if enable_metadata_routing=True (see sklearn.set_config()). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• True: metadata is requested, and passed to predict if provided. The request is ignored if metadata is not provided.
• False: metadata is not requested and the meta-estimator will not pass it to predict.
• None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
• str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (sklearn.utils.metadata_routing.UNCHANGED) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a Pipeline. Otherwise it has no effect.

Parameters

• base_margin (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for base_margin parameter in predict.

• iteration_range (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for iteration_range parameter in predict.

• output_margin (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for output_margin parameter in predict.

• validate_features (str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED) – Metadata routing for validate_features parameter in predict.

• self (DaskXGBRFClassifier)

Returns

self – The updated object.
Return type

object

`set_score_request(*, sample_weight='UNCHANGED')`

Request metadata passed to the `score` method.

Note that this method is only relevant if `enable_metadata_routing=True` (see `sklearn.set_config()`). Please see User Guide on how the routing mechanism works.

The options for each parameter are:

• True: metadata is requested, and passed to `score` if provided. The request is ignored if metadata is not provided.
• False: metadata is not requested and the meta-estimator will not pass it to `score`.
• None: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
• str: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (`sklearn.utils.metadata_routing.UNCHANGED`) retains the existing request. This allows you to change the request for some parameters and not others.

Added in version 1.3.

### Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a `Pipeline`. Otherwise it has no effect.

**Parameters**

- `sample_weight` *(str, True, False, or None, default=sklearn.utils.metadata_routing.UNCHANGED)* – Metadata routing for `sample_weight` parameter in `score`.

- `self` *(DaskXGBRFClassifier)*

**Returns**

- `self` – The updated object.

**Return type**

object

### PySpark API

PySpark XGBoost integration interface

```python
class xgboost.spark.SparkXGBClассifier(*, features_col='features', label_col='label', prediction_col='prediction', probability_col='probability', raw_prediction_col='rawPrediction', pred_contrib_col=None, validation_indicator_col=None, weight_col=None, base_margin_col=None, num_workers=1, use_gpu=None, device=None, force_repartition=False, repartition_random_shuffle=False, enable_sparse_data_optim=False, **kwargs)
```

1.10. XGBoost Python Package
SparkXGBClassifier is a PySpark ML estimator. It implements the XGBoost classification algorithm based on XGBoost python library, and it can be used in PySpark Pipeline and PySpark ML meta algorithms like - CrossValidator/TrainValidationSplit/OneVsRest

SparkXGBClassifier automatically supports most of the parameters in xgboost.XGBClassifier constructor and most of the parameters used in xgboost.XGBClassifier.fit() and xgboost.XGBClassifier.predict() method.

To enable GPU support, set device to cuda or gpu.

SparkXGBClassifier doesn’t support setting base_margin explicitly as well, but support another param called base_margin_col. see doc below for more details.

SparkXGBClassifier doesn’t support setting output_margin, but we can get output margin from the raw prediction column. See raw_prediction_col param doc below for more details.

SparkXGBClassifier doesn’t support validate_features and output_margin param.

SparkXGBClassifier doesn’t support setting nthread xgboost param, instead, the nthread param for each xgboost worker will be set equal to spark.task.cpus config value.

Parameters

- **features_col (str | List[str])** – When the value is string, it requires the features column name to be vector type. When the value is a list of string, it requires all the feature columns to be numeric types.
- **label_col (str)** – Label column name. Default to “label”.
- **prediction_col (str)** – Prediction column name. Default to “prediction”
- **probability_col (str)** – Column name for predicted class conditional probabilities. Default to probabilityCol
- **raw_prediction_col (str)** – The output_margin=True is implicitly supported by the rawPredictionCol output column, which is always returned with the predicted margin values.
- **pred_contrib_col (pyspark.ml.param.Param[str])** – Contribution prediction column name.
- **validation_indicator_col (str | None)** – For params related to xgboost.XGBClassifier training with evaluation dataset’s supervision, set xgboost.spark.SparkXGBClassifier.validation_indicator_col parameter instead of setting the eval_set parameter in xgboost.XGBClassifier fit method.
- **weight_col (str | None)** – To specify the weight of the training and validation dataset, set xgboost.spark.SparkXGBClassifier.weight_col parameter instead of setting sample_weight and sample_weight_eval_set parameter in xgboost.XGBClassifier fit method.
- **base_margin_col (str | None)** – To specify the base margins of the training and validation dataset, set xgboost.spark.SparkXGBClassifier.base_margin_col parameter instead of setting base_margin and base_margin_eval_set in the xgboost.XGBClassifier fit method.
- **num_workers (int)** – How many XGBoost workers to be used to train. Each XGBoost worker corresponds to one spark task.
- **use_gpu (bool | None)** – Deprecated since version 2.0.0. Use device instead.
• **device** *(str | None)* – Added in version 2.0.0.

Device for XGBoost workers, available options are *cpu*, *cuda*, and *gpu*.

• **force_repartition** *(bool)* – Boolean value to specify if forcing the input dataset to be repartitioned before XGBoost training.

• **repartition_random_shuffle** *(bool)* – Boolean value to specify if randomly shuffling the dataset when repartitioning is required.

• **enable_sparse_data_optim** *(bool)* – Boolean value to specify if enabling sparse data optimization, if True, Xgboost DMatrix object will be constructed from sparse matrix instead of dense matrix.

---

**Note**

The Parameters chart above contains parameters that need special handling. For a full list of parameters, see entries with `Param(parent=...` below.

This API is experimental.

---

**Examples**

```python
>>> from xgboost.spark import SparkXGBClassifier
>>> from pyspark.ml.linalg import Vectors

>>> df_train = spark.createDataFrame([  
...     (Vectors.dense(1.0, 2.0, 3.0), 0, False, 1.0),
...     (Vectors.sparse(3, {1: 1.0, 2: 5.5}), 1, False, 2.0),
...     (Vectors.dense(4.0, 5.0, 6.0), 0, True, 1.0),
...     (Vectors.sparse(3, {1: 6.0, 2: 7.5}), 1, True, 2.0),
... ], ["features", "label", "isVal", "weight"])

>>> df_test = spark.createDataFrame([  
...     (Vectors.dense(1.0, 2.0, 3.0), )
... ], ["features"])

>>> xgb_classifier = SparkXGBClassifier(max_depth=5, missing=0.0,
...     validation_indicator_col='isVal', weight_col='weight',
...     early_stopping_rounds=1, eval_metric='logloss')

>>> xgb_clf_model = xgb_classifier.fit(df_train)

>>> xgb_clf_model.transform(df_test).show()
```

clear *(param)*

Clears a param from the param map if it has been explicitly set.

**Parameters**

param *(Param)*

**Return type**

None

copy *(extra=None)*

Creates a copy of this instance with the same uid and some extra params. The default implementation creates a shallow copy using `copy.copy()`, and then copies the embedded and extra parameters over and returns the copy. Subclasses should override this method if the default approach is not sufficient.
Parameters

• extra (dict, optional) – Extra parameters to copy to the new instance
• self (P)

Returns
Copy of this instance

Return type
Params

explainParam(param)
Explains a single param and returns its name, doc, and optional default value and user-supplied value in a string.

Parameters
param (str | Param)

Return type
str

explainParams()
Returns the documentation of all params with their optionally default values and user-supplied values.

Return type
str

eextractParamMap(extra=None)
Extracts the embedded default param values and user-supplied values, and then merges them with extra values from input into a flat param map, where the latter value is used if there exist conflicts, i.e., with ordering: default param values < user-supplied values < extra.

Parameters
extra (dict, optional) – extra param values

Returns
merged param map

Return type
dict

fit(dataset, params=None)
Fits a model to the input dataset with optional parameters.

Added in version 1.3.0.

Parameters

• dataset (pyspark.sql.DataFrame) – input dataset.
• params (dict or list or tuple, optional) – an optional param map that overrides embedded params. If a list/tuple of param maps is given, this calls fit on each param map and returns a list of models.

Returns
fitted model(s)

Return type
Transformer or a list of Transformer
fitMultiple(dataset, paramMaps)

Fits a model to the input dataset for each param map in paramMaps.
Added in version 2.3.0.

Parameters

  • dataset (pyspark.sql.DataFrame) – input dataset.
  • paramMaps (collections.abc.Sequence) – A Sequence of param maps.

Returns

A thread safe iterable which contains one model for each param map. Each call to next(modelIterator) will return (index, model) where model was fit using paramMaps[index]. index values may not be sequential.

Return type

_FitMultipleIterator

getFeaturesCol()

Gets the value of featuresCol or its default value.

Return type

str

getLabelCol()

Gets the value of labelCol or its default value.

Return type

str

getOrDefault(param)

Gets the value of a param in the user-supplied param map or its default value. Raises an error if neither is set.

Parameters

  param (str | Param[T])

Return type

Any | T

getParam(paramName)

Gets a param by its name.

Parameters

  paramName (str)

Return type

Param

getPredictionCol()

Gets the value of predictionCol or its default value.

Return type

str

getProbabilityCol()

Gets the value of probabilityCol or its default value.

Return type

str
getRawPredictionCol()

Gets the value of rawPredictionCol or its default value.

Return type
str

getValidationIndicatorCol()

Gets the value of validationIndicatorCol or its default value.

Return type
str

getWeightCol()

Gets the value of weightCol or its default value.

Return type
str

hasDefault(param)

Checks whether a param has a default value.

Parameters
param(str | Param[Any])

Return type
bool

hasParam(paramName)

Tests whether this instance contains a param with a given (string) name.

Parameters
paramName(str)

Return type
bool

isDefined(param)

Checks whether a param is explicitly set by user or has a default value.

Parameters
param(str | Param[Any])

Return type
bool

isSet(param)

Checks whether a param is explicitly set by user.

Parameters
param(str | Param[Any])

Return type
bool

classmethod load(path)

Reads an ML instance from the input path, a shortcut of read().load(path).

Parameters
path(str)

Return type
RL
**property params:** List[Param]

Returns all params ordered by name. The default implementation uses `dir()` to get all attributes of type `Param`.

**classmethod read()**

Return the reader for loading the estimator.

**Return type**

`SparkXGBReader`

**save(path)**

Save this ML instance to the given path, a shortcut of `write().save(path)`.

**Parameters**

- `path` (str)

**Return type**

None

**set(param, value)**

Sets a parameter in the embedded param map.

**Parameters**

- `param` (Param)
- `value` (Any)

**Return type**

None

**setParams(**kwargs)**

Set params for the estimator.

**Parameters**

- `kwargs` (Any)

**Return type**

None

**set_device(value)**

Set device, optional value: cpu, cuda, gpu

**Parameters**

- `value` (str)

**Return type**

_SparkXGBParams

**uid**

A unique id for the object.

**write()**

Return the writer for saving the estimator.

**Return type**

`SparkXGBWriter`

**class xgboost.spark.SparkXGBClassifierModel(xgb_sklearn_model=None)**

Bases: `_ClassificationModel`

The model returned by `xgboost.spark.SparkXGBClassifier.fit()`
Note

This API is experimental.

Parameters

xgb_sklearn_model (XGBModel | None)

clear(param)

Clears a param from the param map if it has been explicitly set.

Parameters

param (Param)

Return type

None

copy(extra=None)

Creates a copy of this instance with the same uid and some extra params. The default implementation creates a shallow copy using copy.copy(), and then copies the embedded and extra parameters over and returns the copy. Subclasses should override this method if the default approach is not sufficient.

Parameters

- extra (dict, optional) – Extra parameters to copy to the new instance
- self (P)

Returns

Copy of this instance

Return type

Params

explainParam(param)

Explains a single param and returns its name, doc, and optional default value and user-supplied value in a string.

Parameters

param (str | Param)

Return type

str

explainParams()

Returns the documentation of all params with their optionally default values and user-supplied values.

Return type

str

extractParamMap(extra=None)

Extracts the embedded default param values and user-supplied values, and then merges them with extra values from input into a flat param map, where the latter value is used if there exist conflicts, i.e., with ordering: default param values < user-supplied values < extra.

Parameters

- extra (dict, optional) – extra param values

Returns

merged param map
Return type
dict

getFeaturesCol()
Gets the value of featuresCol or its default value.

Return type
str

g.getLabelCol()
Gets the value of labelCol or its default value.

Return type
str

gOrDefault(param)
Gets the value of a param in the user-supplied param map or its default value. Raises an error if neither is set.

Parameters
param (str | Param[T])

Return type
Any | T

gParam(paramName)
Gets a param by its name.

Parameters
paramName (str)

Return type
Param

gPredictionCol()
Gets the value of predictionCol or its default value.

Return type
str

gProbabilityCol()
Gets the value of probabilityCol or its default value.

Return type
str

gRawPredictionCol()
Gets the value of rawPredictionCol or its default value.

Return type
str

gValidationIndicatorCol()
Gets the value of validationIndicatorCol or its default value.

Return type
str

gWeightCol()
Gets the value of weightCol or its default value.
Return type
str

get_booster()
Return the xgboost.core.Booster instance.

Return type
Booster

get_feature_importances
Get feature importance of each feature. Importance type can be defined as:

• ‘weight’: the number of times a feature is used to split the data across all trees.
• ‘gain’: the average gain across all splits the feature is used in.
• ‘cover’: the average coverage across all splits the feature is used in.
• ‘total_gain’: the total gain across all splits the feature is used in.
• ‘total_cover’: the total coverage across all splits the feature is used in.

Parameters
importance_type (str, default 'weight') – One of the importance types defined above.

Return type
Dict[str, float | List[float]]

hasDefault(param)
Checks whether a param has a default value.

Parameters
param (str | Param[Any])

Return type
bool

hasParam(paramName)
Tests whether this instance contains a param with a given (string) name.

Parameters
paramName (str)

Return type
bool

isDefined(param)
Checks whether a param is explicitly set by user or has a default value.

Parameters
param (str | Param[Any])

Return type
bool

isSet(param)
Checks whether a param is explicitly set by user.

Parameters
param (str | Param[Any])
Return type

bool

classmethod load(path)

Reads an ML instance from the input path, a shortcut of read().load(path).

Parameters

path (str)

Return type

RL

property params:

List[Param]

Returns all params ordered by name. The default implementation uses dir() to get all attributes of type Param.

classmethod read()

Return the reader for loading the model.

Return type

SparkXGBModelReader

save(path)

Save this ML instance to the given path, a shortcut of ‘write().save(path)’.

Parameters

path (str)

Return type

None

set(param, value)

Sets a parameter in the embedded param map.

Parameters

• param (Param)

• value (Any)

Return type

None

set_device(value)

Set device, optional value: cpu, cuda, gpu

Parameters

value (str)

Return type

_SparkXGBParams

transform(dataset, params=None)

Transforms the input dataset with optional parameters.

Added in version 1.3.0.

Parameters

• dataset (pyspark.sql.DataFrame) – input dataset

• params (dict, optional) – an optional param map that overrides embedded params.
Returns
transformed dataset

Return type
pyspark.sql.DataFrame

uid
A unique id for the object.

write()
Return the writer for saving the model.

Return type
SparkXGBModelWriter

class xgboost.spark.SparkXGBRegressor(*, features_col='features', label_col='label',
prediction_col='prediction', pred_contrib_col=None,
validation_indicator_col=None, weight_col=None,
base_margin_col=None, num_workers=1, use_gpu=None,
device=None, force_repartition=False,
repartition_random_shuffle=False,
enable_sparse_data_optim=False, **kwargs)

Bases: _SparkXGBEstimator

SparkXGBRegressor is a PySpark ML estimator. It implements the XGBoost regression algorithm based on
XGBoost python library, and it can be used in PySpark Pipeline and PySpark ML meta algorithms like -
CrossValidator/ - TrainValidationSplit/ - OneVsRest

SparkXGBRegressor automatically supports most of the parameters in xgboost.XGBRegressor constructor and most of the parameters used in xgboost.XGBRegressor.fit() and xgboost.XGBRegressor.
predict() method.

To enable GPU support, set device to cuda or gpu.

SparkXGBRegressor doesn’t support setting base_margin explicitly as well, but support another param called
base_margin_col. see doc below for more details.

SparkXGBRegressor doesn’t support validate_features and output_margin param.

SparkXGBRegressor doesn’t support setting nthread xgboost param, instead, the nthread param for each xgboost
worker will be set equal to spark.task.cpus config value.

Parameters

• features_col (str | List[str]) – When the value is string, it requires the features
column name to be vector type. When the value is a list of string, it requires all the feature
columns to be numeric types.

• label_col (str) – Label column name. Default to “label”.

• prediction_col (str) – Prediction column name. Default to “prediction”

• pred_contrib_col (pyspark.ml.param.Param[str]) – Contribution prediction col-
umn name.

• validation_indicator_col (str | None) – For params related to xg-
boost.XGBRegressor training with evaluation dataset’s supervision, set xgboost.
spark.SparkXGBRegressor.validation_indicator_col parameter instead of setting the
eval_set parameter in xgboost.XGBRegressor fit method.
- **weight_col** *(str | None)* – To specify the weight of the training and validation dataset, set `xgboost.spark.SparkXGBRegressor.weight_col` parameter instead of setting `sample_weight` and `sample_weight_eval_set` parameter in `xgboost.XGBRegressor` fit method.

- **base_margin_col** *(str | None)* – To specify the base margins of the training and validation dataset, set `xgboost.spark.SparkXGBRegressor.base_margin_col` parameter instead of setting `base_margin` and `base_margin_eval_set` in the `xgboost.XGBRegressor` fit method.

- **num_workers** *(int)* – How many XGBoost workers to be used to train. Each XGBoost worker corresponds to one spark task.

- **use_gpu** *(bool | None)* – Deprecated since version 2.0.0. Use `device` instead.

- **device** *(str | None)* – Added in version 2.0.0. Device for XGBoost workers, available options are `cpu`, `cuda`, and `gpu`.

- **force_repartition** *(bool)* – Boolean value to specify if forcing the input dataset to be repartitioned before XGBoost training.

- **repartition_random_shuffle** *(bool)* – Boolean value to specify if randomly shuffling the dataset when repartitioning is required.

- **enable_sparse_data_optim** *(bool)* – Boolean value to specify if enabling sparse data optimization, if True, Xgboost DMatrix object will be constructed from sparse matrix instead of dense matrix.

---

### Note

The Parameters chart above contains parameters that need special handling. For a full list of parameters, see entries with `Param(parent=...` below.

This API is experimental.

### Examples

```python
>>> from xgboost.spark import SparkXGBRegressor
>>> from pyspark.ml.linalg import Vectors

>>> df_train = spark.createDataFrame([
...    (Vectors.dense(1.0, 2.0, 3.0), 0, False, 1.0),
...    (Vectors.sparse(3, {1: 1.0, 2: 5.5}), 1, False, 2.0),
...    (Vectors.dense(4.0, 5.0, 6.0), 2, True, 1.0),
...    (Vectors.sparse(3, {1: 6.0, 2: 7.5}), 3, True, 2.0),
... ], ["features", "label", "isVal", "weight"])

>>> df_test = spark.createDataFrame([
...    (Vectors.dense(1.0, 2.0, 3.0), ),
...    (Vectors.sparse(3, {1: 1.0, 2: 5.5}), )
... ], ["features"])

>>> xgb_regressor = SparkXGBRegressor(max_depth=5, missing=0.0,
...    validation_indicator_col='isVal', weight_col='weight',
...    early_stopping_rounds=1, eval_metric='rmse')
```

(continues on next page)
clear(param)
Clears a param from the param map if it has been explicitly set.

Parameters
param (Param)

Return type
None

copy(extra=None)
Creates a copy of this instance with the same uid and some extra params. The default implementation creates a shallow copy using copy.copy(), and then copies the embedded and extra parameters over and returns the copy. Subclasses should override this method if the default approach is not sufficient.

Parameters

• extra (dict, optional) – Extra parameters to copy to the new instance
• self (P)

Returns
Copy of this instance

Return type
Params

extplainParam(param)
Explains a single param and returns its name, doc, and optional default value and user-supplied value in a string.

Parameters
param (str | Param)

Return type
str

extplainParams()
Returns the documentation of all params with their optionally default values and user-supplied values.

Return type
str
	extractParamMap(extra=None)
Extracts the embedded default param values and user-supplied values, and then merges them with extra values from input into a flat param map, where the latter value is used if there exist conflicts, i.e., with ordering: default param values < user-supplied values < extra.

Parameters
extra (dict, optional) – extra param values

Returns
merged param map

Return type
dict
fit(dataset, params=None)

Fits a model to the input dataset with optional parameters.

Added in version 1.3.0.

Parameters

- **dataset** *(pyspark.sql.DataFrame)* – input dataset.
- **params** *(dict or list or tuple, optional)* – an optional param map that overrides embedded params. If a list/tuple of param maps is given, this calls fit on each param map and returns a list of models.

Returns

fitted model(s)

Return type

Transformer or a list of Transformer

fitMultiple(dataset, paramMaps)

Fits a model to the input dataset for each param map in *paramMaps*.

Added in version 2.3.0.

Parameters

- **dataset** *(pyspark.sql.DataFrame)* – input dataset.
- **paramMaps** *(collections.abc.Sequence)* – A Sequence of param maps.

Returns

A thread safe iterable which contains one model for each param map. Each call to *next(modelIterator)* will return *(index, model)* where model was fit using *paramMaps*[index]. *index* values may not be sequential.

Return type

_FitMultipleIterator

getFeaturesCol()

Gets the value of featuresCol or its default value.

Return type

str

getLabelCol()

Gets the value of labelCol or its default value.

Return type

str

getOrDefault(param)

Gets the value of a param in the user-supplied param map or its default value. Raises an error if neither is set.

Parameters

- **param** *(str | Param[T])* 

Return type

Any | T

getParam(paramName)

Gets a param by its name.
Parameters

_ paramName_ (str)

Return type

Param

getAddressCol()

Gets the value of predictionCol or its default value.

Return type

str

getValidationIndicatorCol()

Gets the value of validationIndicatorCol or its default value.

Return type

str

getWeightCol()

Gets the value of weightCol or its default value.

Return type

str

hasDefault(param)

Checks whether a param has a default value.

Parameters

_ param_ (str | Param[Any])

Return type

bool

hasParam(paramName)

Tests whether this instance contains a param with a given (string) name.

Parameters

_ paramName_ (str)

Return type

bool

isDefined(param)

Checks whether a param is explicitly set by user or has a default value.

Parameters

_ param_ (str | Param[Any])

Return type

bool

isSet(param)

Checks whether a param is explicitly set by user.

Parameters

_ param_ (str | Param[Any])

Return type

bool
classmethod load(path)

Reads an ML instance from the input path, a shortcut of read().load(path).

Parameters

path (str)

Return type

RL

property params: List[Param]

Returns all params ordered by name. The default implementation uses dir() to get all attributes of type Param.

classmethod read()

Return the reader for loading the estimator.

Return type

SparkXGBReader

save(path)

Save this ML instance to the given path, a shortcut of ‘write().save(path)’.

Parameters

path (str)

Return type

None

set(param, value)

Sets a parameter in the embedded param map.

Parameters

• param (Param)
• value (Any)

Return type

None

setParams(**kwargs)

Set params for the estimator.

Parameters

kwargs (Any)

Return type

None

set_device(value)

Set device, optional value: cpu, cuda, gpu

Parameters

value (str)

Return type

_SparkXGBParams

uid

A unique id for the object.
write()  
Return the writer for saving the estimator.

Return type  
SparkXGBWriter

class xgboost.spark.SparkXGBRegressorModel(xgb_sklearn_model=None)  
Bases: _SparkXGBModel

The model returned by xgboost.spark.SparkXGBRegressor.fit()

Note  
This API is experimental.

Parameters  
xgb_sklearn_model (XGBModel | None)

clear(param)  
Clears a param from the param map if it has been explicitly set.

Parameters  
param (Param)

Return type  
None

copy(extra=None)  
Creates a copy of this instance with the same uid and some extra params. The default implementation creates a shallow copy using copy.copy(), and then copies the embedded and extra parameters over and returns the copy. Subclasses should override this method if the default approach is not sufficient.

Parameters  
• extra (dict, optional) – Extra parameters to copy to the new instance  
• self (P)

Returns  
Copy of this instance

Return type  
Params

dependentParam(param)  
Explains a single param and returns its name, doc, and optional default value and user-supplied value in a string.

Parameters  
param (str | Param)

Return type  
str

dependentParams()  
Returns the documentation of all params with their optionally default values and user-supplied values.

Return type  
str
**extractParamMap(extra=None)**

Extracts the embedded default param values and user-supplied values, and then merges them with extra values from input into a flat param map, where the latter value is used if there exist conflicts, i.e., with ordering: default param values < user-supplied values < extra.

**Parameters**

extra (dict, optional) – extra param values

**Returns**

merged param map

**Return type**

dict

**getFeaturesCol()**

Gets the value of featuresCol or its default value.

**Return type**

str

**getLabelCol()**

Gets the value of labelCol or its default value.

**Return type**

str

**getOrDefault(param)**

Gets the value of a param in the user-supplied param map or its default value. Raises an error if neither is set.

**Parameters**

param (str | Param[T])

**Return type**

Any | T

**getParam(paramName)**

Gets a param by its name.

**Parameters**

paramName (str)

**Return type**

Param

**getPredictionCol()**

Gets the value of predictionCol or its default value.

**Return type**

str

**getValidationIndicatorCol()**

Gets the value of validationIndicatorCol or its default value.

**Return type**

str

**getWeightCol()**

Gets the value of weightCol or its default value.

**Return type**

str
get_booster()

Return the :class:`xgboost.core.Booster` instance.

Return type
Booster

get_feature_importances(importance_type='weight')

Get feature importance of each feature. Importance type can be defined as:

- ‘weight’: the number of times a feature is used to split the data across all trees.
- ‘gain’: the average gain across all splits the feature is used in.
- ‘cover’: the average coverage across all splits the feature is used in.
- ‘total_gain’: the total gain across all splits the feature is used in.
- ‘total_cover’: the total coverage across all splits the feature is used in.

Parameters
importance_type (str, default 'weight') – One of the importance types defined above.

Return type
Dict[str, float | List[float]]

hasDefault(param)

Checks whether a param has a default value.

Parameters
param (str | Param[Any])

Return type
bool

hasParam(paramName)

Tests whether this instance contains a param with a given (string) name.

Parameters
paramName (str)

Return type
bool

isDefined(param)

Checks whether a param is explicitly set by user or has a default value.

Parameters
param (str | Param[Any])

Return type
bool

isSet(param)

Checks whether a param is explicitly set by user.

Parameters
param (str | Param[Any])

Return type
bool
classmethod load(path)
    Reads an ML instance from the input path, a shortcut of read().load(path).
    Parameters
    path (str)
    Return type
    RL

property params: List[Param]
    Returns all params ordered by name. The default implementation uses dir() to get all attributes of type Param.

classmethod read()
    Return the reader for loading the model.
    Return type
    SparkXGBModelReader

save(path)
    Save this ML instance to the given path, a shortcut of ‘write().save(path)’.
    Parameters
    path (str)
    Return type
    None

set(param, value)
    Sets a parameter in the embedded param map.
    Parameters
    • param (Param)
    • value (Any)
    Return type
    None

set_device(value)
    Set device, optional value: cpu, cuda, gpu
    Parameters
    value (str)
    Return type
    _SparkXGBParams

transform(dataset, params=None)
    Transforms the input dataset with optional parameters.
    Added in version 1.3.0.
    Parameters
    • dataset (pyspark.sql.DataFrame) – input dataset
    • params (dict, optional) – an optional param map that overrides embedded params.
    Returns
    transformed dataset
Return type
pyspark.sql.DataFrame

uid
A unique id for the object.

write()
Return the writer for saving the model.

Return type
SparkXGBModelWriter

class xgboost.spark.SparkXGBRanker(*, features_col='features', label_col='label',
prediction_col='prediction', pred_contrib_col=None,
validation_indicator_col=None, weight_col=None,
base_margin_col=None, qid_col=None, num_workers=1,
use_gpu=None, device=None, force_repartition=False,
repartition_random_shuffle=False, enable_sparse_data_optim=False,
**kwargs)

Bases: _SparkXGBEstimator

SparkXGBRanker is a PySpark ML estimator. It implements the XGBoost ranking algorithm based on XGBoost python library, and it can be used in PySpark Pipeline and PySpark ML meta algorithms like CrossValidator/TrainValidationSplit/OneVsRest

SparkXGBRanker automatically supports most of the parameters in xgboost.XGBRanker constructor and most of the parameters used in xgboost.XGBRanker.fit() and xgboost.XGBRanker.predict() method.

To enable GPU support, set device to cuda or gpu.

SparkXGBRanker doesn’t support setting base_margin explicitly as well, but support another param called base_margin_col. see doc below for more details.

SparkXGBRanker doesn’t support setting output_margin, but we can get output margin from the raw prediction column. See raw_prediction_col param doc below for more details.

SparkXGBRanker doesn’t support validate_features and output_margin param.

SparkXGBRanker doesn’t support setting nthread xgboost param, instead, the nthread param for each xgboost worker will be set equal to spark.task.cpus config value.

Parameters

• features_col (str | List[str]) – When the value is string, it requires the features column name to be vector type. When the value is a list of string, it requires all the feature columns to be numeric types.

• label_col (str) – Label column name. Default to “label”.

• prediction_col (str) – Prediction column name. Default to “prediction”

• pred_contrib_col (pyspark.ml.param.Param[str]) – Contribution prediction column name.

• validation_indicator_col (str | None) – For params related to xgboost.XGBRanker training with evaluation dataset’s supervision, set xgboost.spark.SparkXGBRanker.validation_indicator_col parameter instead of setting the eval_set parameter in xgboost.XGBRanker fit method.

• weight_col (str | None) – To specify the weight of the training and validation dataset, set xgboost.spark.SparkXGBRanker.weight_col parameter instead of setting sample_weight and sample_weight_eval_set parameter in xgboost.XGBRanker fit method.
• **base_margin_col** *(str | None)* – To specify the base margins of the training and validation dataset, set `xgboost.spark.SparkXGBRanker.base_margin_col` parameter instead of setting `base_margin` and `base_margin_eval_set` in the `xgboost.XGBRanker` fit method.

• **qid_col** *(str | None)* – Query id column name.

• **num_workers** *(int)* – How many XGBoost workers to be used to train. Each XGBoost worker corresponds to one spark task.

• **use_gpu** *(bool | None)* – Deprecated since version 2.0.0. Use `device` instead.

• **device** *(str | None)* – Added in version 2.0.0. Device for XGBoost workers, available options are `cpu`, `cuda`, and `gpu`.

• **force_repartition** *(bool)* – Boolean value to specify if forcing the input dataset to be repartitioned before XGBoost training.

• **repartition_random_shuffle** *(bool)* – Boolean value to specify if randomly shuffling the dataset when repartitioning is required.

• **enable_sparse_data_optim** *(bool)* – Boolean value to specify if enabling sparse data optimization, if True, Xgboost DMatrix object will be constructed from sparse matrix instead of dense matrix.

• **Note:** The Parameters chart above contains parameters that need special handling. For a full list of parameters, see entries with `Param(parent=...` below.

• **Note:** – This API is experimental.

### Examples

```python
>>> from xgboost.spark import SparkXGBRanker
>>> from pyspark.ml.linalg import Vectors

>>> ranker = SparkXGBRanker(qid_col="qid")
>>> df_train = spark.createDataFrame([...    [Vectors.dense(1.0, 2.0, 3.0), 0, 0),
    ...    (Vectors.dense(4.0, 5.0, 6.0), 1, 0),
    ...    (Vectors.dense(9.0, 4.0, 8.0), 2, 0),
    ...    (Vectors.sparse(3, {1: 1.0, 2: 5.5}), 0, 1),
    ...    (Vectors.sparse(3, {1: 6.0, 2: 7.5}), 1, 1),
    ...    (Vectors.sparse(3, {1: 8.0, 2: 9.5}), 2, 1),
    ...    ],
    ...    ["features", "label", "qid"],
    ...])
>>> df_test = spark.createDataFrame([...    [Vectors.dense(1.5, 2.0, 3.0), 0, ],
    ...    (Vectors.dense(4.5, 5.0, 6.0), 0, ),
    ...    (Vectors.dense(9.0, 4.5, 8.0), 0, ),
    ...    (Vectors.sparse(3, {1: 1.0, 2: 6.0}), 1, ),
    ...    (Vectors.sparse(3, {1: 6.0, 2: 7.0}), 1, ),
    ...])
```
>>> model = ranker.fit(df_train)
>>> model.transform(df_test).show()

clear(param)

Clears a param from the param map if it has been explicitly set.

Parameters
  param (Param)

Return type
  None

copy(extra=None)

Creates a copy of this instance with the same uid and some extra params. The default implementation creates a shallow copy using copy.copy(), and then copies the embedded and extra parameters over and returns the copy. Subclasses should override this method if the default approach is not sufficient.

Parameters
  • extra (dict, optional) – Extra parameters to copy to the new instance
  • self (P)

Returns
  Copy of this instance

Return type
  Params

explainParam(param)

Explains a single param and returns its name, doc, and optional default value and user-supplied value in a string.

Parameters
  param (str | Param)

Return type
  str

explainParams()

Returns the documentation of all params with their optionally default values and user-supplied values.

Return type
  str

extractParamMap(extra=None)

Extracts the embedded default param values and user-supplied values, and then merges them with extra values from input into a flat param map, where the latter value is used if there exist conflicts, i.e., with ordering: default param values < user-supplied values < extra.

Parameters
  • extra (dict, optional) – extra param values

Returns
  merged param map
Return type
dict

fit(dataset, params=None)
Fits a model to the input dataset with optional parameters.
Added in version 1.3.0.

Parameters
- **dataset** (pyspark.sql.DataFrame) – input dataset.
- **params** (dict or list or tuple, optional) – an optional param map that overrides embedded params. If a list/tuple of param maps is given, this calls fit on each param map and returns a list of models.

Returns
fitted model(s)

Return type
Transformer or a list of Transformer

fitMultiple(dataset, paramMaps)
Fits a model to the input dataset for each param map in paramMaps.
Added in version 2.3.0.

Parameters
- **dataset** (pyspark.sql.DataFrame) – input dataset.
- **paramMaps** (collections.abc.Sequence) – A Sequence of param maps.

Returns
A thread safe iterable which contains one model for each param map. Each call to next(modelIterator) will return (index, model) where model was fit using paramMaps[index]. index values may not be sequential.

Return type
_FitMultipleIterator

getFeaturesCol()
Gets the value of featuresCol or its default value.

Return type
str

getLabelCol()
Gets the value of labelCol or its default value.

Return type
str

getOrDefault(param)
Gets the value of a param in the user-supplied param map or its default value. Raises an error if neither is set.

Parameters
- **param** (str | Param[T])

Return type
Any | T
getParam\((\text{paramName})\)
Gets a param by its name.

Parameters
\begin{itemize}
\item paramName (str)
\end{itemize}

Return type
Param

getPredictionCol()
Gets the value of predictionCol or its default value.

Return type
str

getValidationIndicatorCol()
Gets the value of validationIndicatorCol or its default value.

Return type
str

getWeightCol()
Gets the value of weightCol or its default value.

Return type
str

hasDefault\((\text{param})\)
Checks whether a param has a default value.

Parameters
\begin{itemize}
\item param (str | Param\[Any\])
\end{itemize}

Return type
bool

hasParam\((\text{paramName})\)
Tests whether this instance contains a param with a given (string) name.

Parameters
\begin{itemize}
\item paramName (str)
\end{itemize}

Return type
bool

isDefined\((\text{param})\)
Checks whether a param is explicitly set by user or has a default value.

Parameters
\begin{itemize}
\item param (str | Param\[Any\])
\end{itemize}

Return type
bool

isSet\((\text{param})\)
Checks whether a param is explicitly set by user.

Parameters
\begin{itemize}
\item param (str | Param\[Any\])
\end{itemize}

Return type
bool
classmethod load(path)
    Reads an ML instance from the input path, a shortcut of read().load(path).
    Parameters
    path (str)
    Return type
    RL

property params: List[Param]
    Returns all params ordered by name. The default implementation uses dir() to get all attributes of type Param.

classmethod read()
    Return the reader for loading the estimator.
    Return type
    SparkXGBReader

save(path)
    Save this ML instance to the given path, a shortcut of ‘write().save(path)’.
    Parameters
    path (str)
    Return type
    None

set(param, value)
    Sets a parameter in the embedded param map.
    Parameters
    • param (Param)
    • value (Any)
    Return type
    None

setParams(**kwargs)
    Set params for the estimator.
    Parameters
    kwargs (Any)
    Return type
    None

set_device(value)
    Set device, optional value: cpu, cuda, gpu
    Parameters
    value (str)
    Return type
    _SparkXGBParams

uid
    A unique id for the object.
write()

Return the writer for saving the estimator.

Return type

SparkXGBWriter
class xgboost.spark.SparkXGBRankerModel(xgb_sklearn_model=None)

Bases: _SparkXGBModel

The model returned by xgboost.spark.SparkXGBRanker.fit()

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>This API is experimental.</td>
</tr>
</tbody>
</table>

Parameters

xgb_sklearn_model (XGBModel | None)

clear(param)

Clears a param from the param map if it has been explicitly set.

Parameters

param (Param)

Return type

None
copy(extra=None)

Creates a copy of this instance with the same uid and some extra params. The default implementation creates a shallow copy using copy.copy(), and then copies the embedded and extra parameters over and returns the copy. Subclasses should override this method if the default approach is not sufficient.

Parameters

• extra (dict, optional) – Extra parameters to copy to the new instance

• self (P)

Returns

Copy of this instance

Return type

Params

explainParam(param)

Explains a single param and returns its name, doc, and optional default value and user-supplied value in a string.

Parameters

param (str | Param)

Return type

str

del()

Removes an item from the model (e.g., the deep learning model).

Return type

None
extractParamMap(extra=None)
Extracts the embedded default param values and user-supplied values, and then merges them with extra values from input into a flat param map, where the latter value is used if there exist conflicts, i.e., with ordering: default param values < user-supplied values < extra.

Parameters
extra (dict, optional) – extra param values

Returns
merged param map

Return type
dict

getFeaturesCol()
Gets the value of featuresCol or its default value.

Return type
str

getLabelCol()
Gets the value of labelCol or its default value.

Return type
str

getOrDefault(param)
 Gets the value of a param in the user-supplied param map or its default value. Raises an error if neither is set.

Parameters
param (str | Param[T])

Return type
Any | T

getParam(paramName)
Gets a param by its name.

Parameters
paramName (str)

Return type
Param

getPredictionCol()
Gets the value of predictionCol or its default value.

Return type
str

getValidationIndicatorCol()
Gets the value of validationIndicatorCol or its default value.

Return type
str

getWeightCol()
 Gets the value of weightCol or its default value.

Return type
str
get_booster()

Return the xgboost.core.Booster instance.

Return type

Booster

get_feature_importances(importance_type='weight')

Get feature importance of each feature. Importance type can be defined as:

• ‘weight’: the number of times a feature is used to split the data across all trees.
• ‘gain’: the average gain across all splits the feature is used in.
• ‘cover’: the average coverage across all splits the feature is used in.
• ‘total_gain’: the total gain across all splits the feature is used in.
• ‘total_cover’: the total coverage across all splits the feature is used in.

Parameters

importance_type (str, default 'weight') – One of the importance types defined above.

Return type

Dict[str, float | List[float]]

hasDefault(param)

Checks whether a param has a default value.

Parameters

param (str | Param[Any])

Return type

bool

hasParam(paramName)

Tests whether this instance contains a param with a given (string) name.

Parameters

paramName (str)

Return type

bool

isDefined(param)

Checks whether a param is explicitly set by user or has a default value.

Parameters

param (str | Param[Any])

Return type

bool

isSet(param)

Checks whether a param is explicitly set by user.

Parameters

param (str | Param[Any])

Return type

bool
classmethod **load**(*path*)

Reads an ML instance from the input path, a shortcut of `read().load(path)`.

**Parameters**

- **path** *(str)*

**Return type**

*RL*

**property** **params**: List[Param]

Returns all params ordered by name. The default implementation uses `dir()` to get all attributes of type Param.

classmethod **read**()

Return the reader for loading the model.

**Return type**

*SparkXGBModelReader*

**save**(*path*)

Save this ML instance to the given path, a shortcut of `write().save(path)`.

**Parameters**

- **path** *(str)*

**Return type**

*None*

**set**(param, value)

Sets a parameter in the embedded param map.

**Parameters**

- **param** *(Param)*
- **value** *(Any)*

**Return type**

*None*

**set_device**(*value*)

Set device, optional value: cpu, cuda, gpu

**Parameters**

- **value** *(str)*

**Return type**

*_SparkXGBParams*

**transform**(dataset, params=None)

Transforms the input dataset with optional parameters.

Added in version 1.3.0.

**Parameters**

- **dataset** *(pyspark.sql.DataFrame)* – input dataset
- **params** *(dict, optional)* – an optional param map that overrides embedded params.

**Returns**

transformation dataset

---

1.10. XGBoost Python Package 341
Callback Functions

This document gives a basic walkthrough of callback API used in XGBoost Python package. In XGBoost 1.3, a new callback interface is designed for Python package, which provides the flexibility of designing various extension for training. Also, XGBoost has a number of pre-defined callbacks for supporting early stopping, checkpoints etc.

Using builtin callbacks

By default, training methods in XGBoost have parameters like early_stopping_rounds and verbose/verbose_eval, when specified the training procedure will define the corresponding callbacks internally. For example, when early_stopping_rounds is specified, EarlyStopping callback is invoked inside iteration loop. You can also pass this callback function directly into XGBoost:

```python
D_train = xgb.DMatrix(X_train, y_train)
D_valid = xgb.DMatrix(X_valid, y_valid)

# Define a custom evaluation metric used for early stopping.
def eval_error_metric(predt, dtrain: xgb.DMatrix):
    label = dtrain.get_label()
    r = np.zeros(predt.shape)
    gt = predt > 0.5
    r[gt] = 1 - label[gt]
    le = predt <= 0.5
    r[le] = label[le]
    return 'CustomErr', np.sum(r)

# Specify which dataset and which metric should be used for early stopping.
early_stop = xgb.callback.EarlyStopping(rounds=early_stopping_rounds,
                                          metric_name='CustomErr',
                                          data_name='Valid')

booster = xgb.train(
    {'objective': 'binary:logistic',
     'eval_metric': ['error', 'rmse'],
     'tree_method': 'hist'}, D_train,
    evals=[(D_train, 'Train'), (D_valid, 'Valid')],
    feval=eval_error_metric,
    num_boost_round=1000,
    callbacks=[early_stop],
    verbose_eval=False)
```

(continues on next page)
dump = booster.get_dump(dump_format='json')
assert len(early_stop.stopping_history['Valid']['CustomErr']) == len(dump)

Defining your own callback

XGBoost provides an callback interface class: `TrainingCallback`, user defined callbacks should inherit this class and override corresponding methods. There’s a working example in `Demo for using and defining callback functions`.

Model

Slice tree model

When booster is set to `gbtree` or `dart`, XGBoost builds a tree model, which is a list of trees and can be sliced into multiple sub-models.

```python
from sklearn.datasets import make_classification
num_classes = 3
X, y = make_classification(n_samples=1000, n_informative=5,
                           n_classes=num_classes)
dtrain = xgb.DMatrix(data=X, label=y)
num_parallel_tree = 4
num_boost_round = 16
# total number of built trees is num_parallel_tree * num_classes * num_boost_round

# We build a boosted random forest for classification here.
booster = xgb.train({
    'num_parallel_tree': 4, 'subsample': 0.5, 'num_class': 3},
    num_boost_round=num_boost_round, dtrain=dtrain)

# This is the sliced model, containing [3, 7) forests
# step is also supported with some limitations like negative step is invalid.

# Access individual tree layer
trees = [for _ in booster]
assert len(trees) == num_boost_round
```

The sliced model is a copy of selected trees, that means the model itself is immutable during slicing. This feature is the basis of `save_best` option in early stopping callback. See `Demo for prediction using individual trees and model slices` for a worked example on how to combine prediction with sliced trees.

Note

The returned model slice doesn’t contain attributes like `best_iteration` and `best_score`. 

1.10. XGBoost Python Package 343
XGBoost Python Feature Walkthrough

This is a collection of examples for using the XGBoost Python package.

Demo for using xgboost with sklearn

```python
import multiprocessing

from sklearn.datasets import fetch_california_housing
from sklearn.model_selection import GridSearchCV

import xgboost as xgb

if __name__ == '__main__':
    print("Parallel Parameter optimization")
    X, y = fetch_california_housing(return_X_y=True)
    # Make sure the number of threads is balanced.
    xgb_model = xgb.XGBRegressor(
        n_jobs=multiprocessing.cpu_count() // 2, tree_method="hist"
    )
    clf = GridSearchCV(
        xgb_model,
        {"max_depth": [2, 4, 6], "n_estimators": [50, 100, 200]},
        verbose=1,
        n_jobs=2,
    )
    clf.fit(X, y)
    print(clf.best_score_)
    print(clf.best_params_)
```

Demo for obtaining leaf index

```python
import os

import xgboost as xgb

# load data in do training
CURRENT_DIR = os.path.dirname(__file__)
dtrain = xgb.DMatrix(
    os.path.join(CURRENT_DIR, ".\data\agaricus.txt.train?format=libsvm")
)
dtest = xgb.DMatrix(
    os.path.join(CURRENT_DIR, ".\data\agaricus.txt.test?format=libsvm")
)
param = {"max_depth": 2, "eta": 1, "objective": "binary:logistic"}
watchlist = [(dtest, "eval"), (dtrain, "train")]
num_round = 3
bst = xgb.train(param, dtrain, num_round, watchlist)

print("start testing predict the leaf indices")
```

(continues on next page)
# predict using first 2 tree
leafindex = bst.predict(
    dtest, iteration_range=(0, 2), pred_leaf=True, strict_shape=True
)
print(leafindex.shape)
print(leafindex)

# predict all trees
leafindex = bst.predict(dtest, pred_leaf=True)
print(leafindex.shape)

This script demonstrate how to access the eval metrics

```python
import os
import xgboost as xgb

CURRENT_DIR = os.path.dirname(__file__)
dtrain = xgb.DMatrix(
    os.path.join(CURRENT_DIR, "../data/agaricus.txt.train?format=libsvm")
)
dtest = xgb.DMatrix(
    os.path.join(CURRENT_DIR, "../data/agaricus.txt.test?format=libsvm")
)

param = [
    ("max_depth", 2),
    ("objective", "binary:logistic"),
    ("eval_metric", "logloss"),
    ("eval_metric", "error"),
]

num_round = 2
watchlist = [(dtest, "eval"), (dtrain, "train")]

evals_result = {}
bst = xgb.train(param, dtrain, num_round, watchlist, evals_result=evals_result)

print("Access logloss metric directly from evals_result:")
print(evals_result["eval"]["logloss"])

print(""")
print("Access metrics through a loop:")
for e_name, e_mtrs in evals_result.items():
    print("- {}".format(e_name))
    for e_mtr_name, e_mtr_vals in e_mtrs.items():
        print("    - {}".format(e_mtr_name))
        print("        - {}".format(e_mtr_vals))

print("""
print("Access complete dictionary:")
```

(continues on next page)
print(evals_result)

Demo for gamma regression

```python
import numpy as np
import xgboost as xgb

# this script demonstrates how to fit gamma regression model (with log link function)
# in xgboost, before running the demo you need to generate the autoclaims dataset
# by running gen_autoclaims.R located in xgboost/demo/data.

data = np.genfromtxt('..data/autoclaims.csv', delimiter=',',
                      encoding=None, skip_header=0, dtype=float,
                      encoding=None, errors=None, warn作业：

dtrain = xgb.DMatrix(data[0:4741, 0:34], data[0:4741, 34])
dtest = xgb.DMatrix(data[4741:6773, 0:34], data[4741:6773, 34])

# for gamma regression, we need to set the objective to 'reg:gamma', it also suggests
# to set the base_score to a value between 1 to 5 if the number of iteration is small
param = {'objective': 'reg:gamma', 'base_score': 3}

# the rest of settings are the same
watchlist = [(dtest, 'eval'), (dtrain, 'train')]
num_round = 30

# training and evaluation
bst = xgb.train(param, dtrain, num_round, watchlist)
preds = bst.predict(dtest)
labels = dtest.get_label()
print('test deviance=%f' % (2 * np.sum((labels - preds) / preds - np.log(labels) + np.log(preds))))
```

Demo for boosting from prediction

```python
import os
import xgboost as xgb

CURRENT_DIR = os.path.dirname(__file__)
dtrain = xgb.DMatrix(os.path.join(CURRENT_DIR, '..', 'data/agriculture.train?format=libsvm'))
dtest = xgb.DMatrix(os.path.join(CURRENT_DIR, '..', 'data/agriculture.test?format=libsvm'))
watchlist = [(dtest, 'eval'), (dtrain, 'train')]

###
# advanced: start from a initial base prediction
#```
print("start running example to start from a initial prediction")
# specify parameters via map, definition are same as c++ version
param = {"max_depth": 2, "eta": 1, "objective": "binary:logistic"}
# train xgboost for 1 round
bst = xgb.train(param, dtrain, 1, watchlist)
# Note: we need the margin value instead of transformed prediction in
# set_base_margin
# do predict with output_margin=True, will always give you margin values
# before logistic transformation
ptrain = bst.predict(dtrain, output_margin=True)
pptest = bst.predict(dtest, output_margin=True)
dtrain.set_base_margin(ptrain)
dtest.set_base_margin(pptest)

print("this is result of running from initial prediction")
bst = xgb.train(param, dtrain, 1, watchlist)

Demo for accessing the xgboost eval metrics by using sklearn interface

import numpy as np
from sklearn.datasets import make_hastie_10_2

import xgboost as xgb

X, y = make_hastie_10_2(n_samples=2000, random_state=42)

# Map labels from {-1, 1} to {0, 1}
labels, y = np.unique(y, return_inverse=True)

X_train, X_test = X[:1600], X[1600:]
y_train, y_test = y[:1600], y[1600:]

param_dist = {"objective": "binary:logistic", "n_estimators": 2}

clf = xgb.XGBModel(**param_dist,
    eval_metric="logloss",
)
# Or you can use: clf = xgb.XGBClassifier(**param_dist)

clf.fit(
    X_train,
    y_train,
    eval_set=[(X_train, y_train), (X_test, y_test)],
    verbose=True,
)

# Load evals result by calling the evals_result() function
evals_result = clf.evals_result()
print("Access logloss metric directly from validation_0:")
print(evals_result["validation_0"]["logloss"]

print("\n")
print("Access metrics through a loop:")
for e_name, e_mtrs in evals_result.items():
    print("- {}\n".format(e_name))
    for e_mtr_name, e_mtr_vals in e_mtrs.items():
        print("- {}\n".format(e_mtr_name))
        print("- {}\n".format(e_mtr_vals))

print("\n")
print("Access complete dict:")
print(evals_result)

---

Demo for using feature weight to change column sampling

Added in version 1.3.0.

```python
import argparse
import numpy as np
from matplotlib import pyplot as plt
import xgboost

def main(args: argparse.Namespace) -> None:
    kRows = 4196
    kCols = 10

    X = rng.randn(kRows, kCols)
    y = rng.randn(kRows)
    fw = np.ones(shape=(kCols,))
    for i in range(kCols):
        fw[i] *= float(i)

    dtrain = xgboost.DMatrix(X, y)
    dtrain.set_info(feature_weights=fw)

    # Perform column sampling for each node split evaluation, the sampling process is
    # weighted by feature weights.
    bst = xgboost.train(
        {"tree_method": "hist", "colsample_by_node": 0.2},
        dtrain,
        num_boost_round=10,
        evals=[(dtrain, "d")],
    )

    feature_map = bst.get_fscore()
```
# feature zero has 0 weight
assert feature_map.get("f0", None) is None
assert max(feature_map.values()) == feature_map.get("f9")

if args.plot:
    xgboost.plot_importance(bst)
    plt.show()

if __name__ == '__main__':
    parser = argparse.ArgumentParser()
    parser.add_argument("--plot", type=int, default=1, help="Set to 0 to disable plotting the evaluation history.",
    )
    args = parser.parse_args()
    main(args)

Demo for GLM

```
import os

import xgboost as xgb

##
# this script demonstrate how to fit generalized linear model in xgboost
# basically, we are using linear model, instead of tree for our boosters
##
CURRENT_DIR = os.path.dirname(__file__)
dtrain = xgb.DMatrix(os.path.join(CURRENT_DIR, '../data/agaricus.txt.train?format=libsvm'))
dtest = xgb.DMatrix(os.path.join(CURRENT_DIR, '../data/agaricus.txt.test?format=libsvm'))
# change booster to gblinear, so that we are fitting a linear model
# alpha is the L1 regularizer
# lambda is the L2 regularizer
# you can also set lambda_bias which is L2 regularizer on the bias term
param = {
    "objective": "binary:logistic",
    "booster": "gblinear",
    "alpha": 0.0001,
    "lambda": 1,
}
# normally, you do not need to set eta (step_size)
```
XGBoost uses a parallel coordinate descent algorithm (shotgun), there could be affection on convergence with parallelization on certain cases. Setting eta to be a smaller value, e.g. 0.5 can make the optimization more stable. 

```python
param['eta'] = 1
```

```
##
## the rest of settings are the same
##
watchlist = [(dtest, "eval"), (dtrain, "train")]
num_round = 4
bst = xgb.train(param, dtrain, num_round, watchlist)
preds = bst.predict(dtest)
labels = dtest.get_label()
print(
    "error=%f"
    % (sum(1 for i in range(len(preds)) if int(preds[i] > 0.5) != labels[i])
        / float(len(preds))
)
```

Demo for prediction using number of trees

```python
import os
import numpy as np
from sklearn.datasets import load_svmlight_file
import xgboost as xgb

CURRENT_DIR = os.path.dirname(__file__)
train = os.path.join(CURRENT_DIR, "../data/agaricus.txt.train")
test = os.path.join(CURRENT_DIR, "../data/agaricus.txt.test")

def native_interface():
    # load data in do training
    dtrain = xgb.DMatrix(train + "?format=libsvm")
dtest = xgb.DMatrix(test + "?format=libsvm")
param = {"max_depth": 2, "eta": 1, "objective": "binary:logistic"}
watchlist = [(dtest, "eval"), (dtrain, "train")]
num_round = 3
bst = xgb.train(param, dtrain, num_round, watchlist)

    print("start testing prediction from first n trees")
    # predict using first 1 tree
    label = dtest.get_label()
    ypred1 = bst.predict(dtest, iteration_range=(0, 1))
    # by default, we predict using all the trees
    ypred2 = bst.predict(dtest)
```

(continues on next page)
Getting started with XGBoost

This is a simple example of using the native XGBoost interface, there are other interfaces in the Python package like scikit-learn interface and Dask interface.

See Python Package Introduction and XGBoost Tutorials for other references.

```python
import os
import pickle

import numpy as np
from sklearn.datasets import load_svmlight_file

import xgboost as xgb

# Make sure the demo knows where to load the data.
CURRENT_DIR = os.path.dirname(os.path.abspath(__file__)).
XGBOOST_ROOT_DIR = os.path.dirname(os.path.dirname(CURRENT_DIR)).
DEMO_DIR = os.path.join(XGBOOST_ROOT_DIR, "demo")

# X is a scipy csr matrix, XGBoost supports many other input types,
```
X, y = load_svmlight_file(os.path.join(DEMO_DIR, "data", "agaricus.txt.train"))
dtrain = xgb.DMatrix(X, y)

# validation set
X_test, y_test = load_svmlight_file(os.path.join(DEMO_DIR, "data", "agaricus.txt.test"))
dtest = xgb.DMatrix(X_test, y_test)

# specify parameters via map, definition are same as c++ version
param = {"max_depth": 2, "eta": 1, "objective": "binary:logistic"}

# specify validations set to watch performance
watchlist = [(dtest, "eval"), (dtrain, "train")]

# number of boosting rounds
num_round = 2
bst = xgb.train(param, dtrain, num_boost_round=num_round, evals=watchlist)

# run prediction
preds = bst.predict(dtest)
labels = dtest.get_label()
print("error=%f" % (sum(1 for i in range(len(preds)) if int(preds[i] > 0.5) != labels[i]) / float(len(preds))))
bst.save_model("model-0.json")

# dump model
bst.dump_model("dump.raw.txt")

# dump model with feature map
bst.dump_model("dump.nice.txt", os.path.join(DEMO_DIR, "data/featmap.txt"))

# save dmatrix into binary buffer
dtest.save_binary("dtest.dmatrix")
# save model
bst.save_model("model-1.json")
# load model and data in
bst2 = xgb.Booster(model_file="model-1.json")
dtest2 = xgb.DMatrix("dtest.dmatrix")
preds2 = bst2.predict(dtest2)

assert they are the same
assert np.sum(np.abs(preds2 - preds)) == 0

# alternatively, you can pickle the booster
pk = pickle.dumps(bst2)
# load model and data in
bst3 = pickle.loads(pk)
preds3 = bst3.predict(dtest2)

assert they are the same
assert np.sum(np.abs(preds3 - preds)) == 0
Collection of examples for using sklearn interface

For an introduction to XGBoost’s scikit-learn estimator interface, see Using the Scikit-Learn Estimator Interface.

Getting started with categorical data

Experimental support for categorical data.

In before, users need to run an encoder themselves before passing the data into XGBoost, which creates a sparse matrix and potentially increase memory usage. This demo showcases the experimental categorical data support, more advanced features are planned.

    Added in version 1.5.0.

Demo for using data iterator with Quantile DMatrix

Added in version 1.2.0.

The demo that defines a customized iterator for passing batches of data into `xgboost.QuantileDMatrix` and use this QuantileDMatrix for training. The feature is used primarily designed to reduce the required GPU memory for training on distributed environment.

After going through the demo, one might ask why don't we use more native Python iterator? That's because XGBoost requires a `reset` function, while using `itertools.tee` might incur significant memory usage according to:

https://docs.python.org/3/library/itertools.html#itertools.tee.

```python
import cupy
import numpy

import xgboost

COLS = 64
ROWS_PER_BATCH = 1000  # data is split by rows
BATCHES = 32

class IterForDMatrixDemo(xgboost.core.DataIter):
    """A data iterator for XGBoost DMatrix.
    `reset` and `next` are required for any data iterator, other functions here
    are utilities for demonstration's purpose.
    """
    def __init__(self):
        """Generate some random data for demonstration.
        Actual data can be anything that is currently supported by XGBoost.
        """
        self.rows = ROWS_PER_BATCH
        self.cols = COLS
        rng = cupy.random.RandomState(numpy.uint64(1994))
        self._data = [rng.randn(self.rows, self.cols)] * BATCHES
        self._labels = [rng.randn(self.rows)] * BATCHES
        self._weights = [rng.uniform(size=self.rows)] * BATCHES

        self.it = 0  # set iterator to 0
        super().__init__()

    def as_array(self):
        return cupy.concatenate(self._data)

    def as_array_labels(self):
        return cupy.concatenate(self._labels)

    def as_array_weights(self):
        return cupy.concatenate(self._weights)
```

(continues on next page)
```python
def data(self):
    """Utility function for obtaining current batch of data."""
    return self._data[self.it]

def labels(self):
    """Utility function for obtaining current batch of label."""
    return self._labels[self.it]

def weights(self):
    return self._weights[self.it]

def reset(self):
    """Reset the iterator""
    self.it = 0

def next(self, input_data):
    """Yield next batch of data."""
    if self.it == len(self._data):
        # Return 0 when there's no more batch.
        return 0
    input_data(data=self.data(), label=self.labels(), weight=self.weights())
    self.it += 1
    return 1

def main():
    rounds = 100
    it = IterForDMatrixDemo()

    # Use iterator, must be 'QuantileDMatrix'.
    # In this demo, the input batches are created using cupy, and the data processing
    # (quantile sketching) will be performed on GPU. If data is loaded with CPU based
    # data structures like numpy or pandas, then the processing step will be performed
    # on CPU instead.
    m_with_it = xgboost.QuantileDMatrix(it)

    # Use regular DMatrix.
    m = xgboost.DMatrix(
        it.as_array(), it.as_array_labels(), weight=it.as_array_weights()
    )

    assert m_with_it.num_col() == m.num_col()
    assert m_with_it.num_row() == m.num_row()

```

1.10. XGBoost Python Package
Train XGBoost with cat_in_the_dat dataset

A simple demo for categorical data support using dataset from Kaggle categorical data tutorial.
The excellent tutorial is at: https://www.kaggle.com/shahules/an-overview-of-encoding-techniques
And the data can be found at: https://www.kaggle.com/shahules/an-overview-of-encoding-techniques/data

Added in version 1.6.0.

Quantile Regression

Added in version 2.0.0.

The script is inspired by this awesome example in scikit: https://scikit-learn.org/stable/auto_examples/ensemble/plot_gradient_boosting_quantile.html

Note

The feature is only supported using the Python, R, and C packages. In addition, quantile crossing can happen due to limitation in the algorithm.

```python
import argparse
from typing import Dict
import numpy as np
from sklearn.model_selection import train_test_split
import xgboost as xgb

def f(x: np.ndarray) -> np.ndarray:
    """The function to predict."""
    return x * np.sin(x)

def quantile_loss(args: argparse.Namespace) -> None:
    """Train a quantile regression model."""
    # Generate a synthetic dataset for demo, the generate process is from the sklearn example.
    X = np.atleast_2d(rng.uniform(0, 10.0, size=1000)).T
    expected_y = f(X).ravel()
    sigma = 0.5 + X.ravel() / 10.0
    noise = rng.lognormal(sigma=sigma) - np.exp(sigma**2.0 / 2.0)
    y = expected_y + noise
    
    # Train on 0.05 and 0.95 quantiles. The model is similar to multi-class and multi-target models.
    alpha = np.array([0.05, 0.5, 0.95])
    evals_result: Dict[str, Dict] = {}
    
    X_train, X_test, y_train, y_test = train_test_split(X, y, random_state=rng)
    # We will be using the 'hist' tree method, quantile DMatrix can be used to preserve memory (which has nothing to do with quantile regression itself, see its document for details).
    # Do not use the 'exact' tree method for quantile regression, otherwise the performance might drop.
    Xy = xgb.QuantileDMatrix(X_train, y_train)
    # use Xy as a reference
    Xy_test = xgb.QuantileDMatrix(X_test, y_test, ref=Xy)
```

Getting started with learning to rank

Added in version 2.0.0.

This is a demonstration of using XGBoost for learning to rank tasks using the MSLR_10k_letor dataset. For more information about the dataset, please visit its description page.

This is a two-part demo, the first one contains a basic example of using XGBoost to train on relevance degree, and the second part simulates click data and enable the position debiasing training.

For an overview of learning to rank in XGBoost, please see Learning to Rank.

```python

Demo for defining a custom regression objective and metric

Demo for defining customized metric and objective. Notice that for simplicity reason weight is not used in following example. In this script, we implement the Squared Log Error (SLE) objective and RMSLE metric as customized functions, then compare it with native implementation in XGBoost.

See Custom Objective and Evaluation Metric for a step by step walkthrough, with other details.

The SLE objective reduces impact of outliers in training dataset, hence here we also compare its performance with standard squared error.

```python
import argparse
from time import time
from typing import Dict, List, Tuple

XGBoost Dask Feature Walkthrough

This directory contains some demonstrations for using dask with XGBoost. For an overview, see Distributed XGBoost with Dask.
Use scikit-learn regressor interface with CPU histogram tree method

```python
from dask import array as da
from dask.distributed import Client, LocalCluster
from xgboost import dask as dxgb

def main(client: Client) -> dxgb.Booster:
    # generate some random data for demonstration
    n = 100
    m = 10000
    partition_size = 100
    X = da.random.random((m, n), partition_size)
    y = da.random.random(m, partition_size)

    regressor = dxgb.DaskXGBRegressor(verbosity=1, n_estimators=2)
    regressor.set_params(tree_method="hist")
    # assigning client here is optional
    regressor.client = client

    regressor.fit(X, y, eval_set=[[X, y]])
    prediction = regressor.predict(X)

    bst = regressor.get_booster()
    history = regressor.evals_result()

    print("Evaluation history:", history)
    # returned prediction is always a dask array.
    assert isinstance(prediction, da.Array)
    return bst
```

If __name__ == "__main__":
    # or use other clusters for scaling
    with LocalCluster(n_workers=4, threads_per_worker=1) as cluster:
        with Client(cluster) as client:
            main(client)

Use scikit-learn regressor interface with GPU histogram tree method

```python
import dask
from dask import array as da
from dask.distributed import Client

# It's recommended to use dask_cudat for GPU assignment
from dask_cudat import LocalCUDACluster

from xgboost import dask as dxgb
```

(continues on next page)
def main(client: Client) -> dxgb.Booster:
    # Generate some random data for demonstration
    rng = da.random.default_rng(1)

    m = 2**18
    n = 100
    X = rng.uniform(size=(m, n), chunks=(128**2, -1))
    y = X.sum(axis=1)

    regressor = dxgb.DaskXGBRegressor(verbosity=1)
    # Set the device to CUDA
    regressor.set_params(tree_method="hist", device="cuda")
    # Assigning client here is optional
    regressor.client = client

    regressor.fit(X, y, eval_set=[(X, y)])
    prediction = regressor.predict(X)

    bst = regressor.get_booster()
    history = regressor.evals_result()

    print("Evaluation history:", history)
    # returned prediction is always a dask array.
    assert isinstance(prediction, da.Array)
    return bst

if __name__ == "__main__":
    # With dask cuda, one can scale up XGBoost to arbitrary GPU clusters.
    # 'LocalCUDACluster' used here is only for demonstration purpose.
    with LocalCUDACluster() as cluster:
        # Create client from cluster, set the backend to GPU array (cupy).
        with Client(cluster) as client, dask.config.set({"array.backend": "cupy"}):
            main(client)

Example of training with Dask on CPU

from dask import array as da
from dask.distributed import Client, LocalCluster
from xgboost import dask as dxgb
from xgboost.dask import DaskDMatrix

def main(client: Client) -> None:
    # generate some random data for demonstration
    m = 100000
    n = 100
    rng = da.random.default_rng(1)
    X = rng.normal(size=(m, n), chunks=(10000, -1))
y = X.sum(axis=1)

# DaskDMatrix acts like normal DMatrix, works as a proxy for local
# DMatrix scatter around workers.
dtrain = DaskDMatrix(client, X, y)

# Use train method from xgboost.dask instead of xgboost. This
# distributed version of train returns a dictionary containing the
# resulting booster and evaluation history obtained from
# evaluation metrics.
output = dxgb.train(
    client,
    {
        "verbosity": 1,
        "tree_method": "hist",
    },
    dtrain,
    num_boost_round=4,
    evals=[(dtrain, "train")],
)
bst = output["booster"]
history = output["history"]

# you can pass output directly into `predict` too.
prediction = dxgb.predict(client, bst, dtrain)
print("Evaluation history:", history)
print("Error:", da.sqrt((prediction - y) ** 2).mean().compute())

if __name__ == "__main__":
    # or use other clusters for scaling
    with LocalCluster(n_workers=7, threads_per_worker=4) as cluster:
        with Client(cluster) as client:
            main(client)

Example of training survival model with Dask on CPU

```python
import os
import dask.array as da
import dask.dataframe as dd
from dask.distributed import Client, LocalCluster
from xgboost import dask as dxgb
from xgboost.dask import DaskDMatrix

def main(client: Client) -> da.Array:
    # Load an example survival data from CSV into a Dask data frame.
    # The Veterans' Administration Lung Cancer Trial
    # The Statistical Analysis of Failure Time Data by Kalbfleisch J. and Prentice R...
    # (1980)
    CURRENT_DIR = os.path.dirname(__file__)
```

(continues on next page)
df = dd.read_csv(os.path.join(CURRENT_DIR, os.pardir, "data", "veterans_lung_cancer.csv"))

# DaskDMatrix acts like normal DMatrix, works as a proxy for local DMatrix scatter around workers.
# For AFT survival, you'd need to extract the lower and upper bounds for the label and pass them as arguments to DaskDMatrix.
y_lower_bound = df["Survival_label_lower_bound"]
y_upper_bound = df["Survival_label_upper_bound"]
X = df.drop(["Survival_label_lower_bound", "Survival_label_upper_bound"], axis=1)
dtrain = DaskDMatrix(client, X, label_lower_bound=y_lower_bound, label_upper_bound=y_upper_bound)

# Use train method from xgboost.dask instead of xgboost. This distributed version of train returns a dictionary containing the resulting booster and evaluation history obtained from evaluation metrics.
params = {
    "verbosity": 1,
    "objective": "survival:aft",
    "eval_metric": "aft-nloglik",

**GPU Acceleration Demo**

This is a collection of demonstration scripts to showcase the basic usage of GPU. Please see *XGBoost GPU Support* for more info. There are other demonstrations for distributed GPU training using dask or spark.

**Using xgboost on GPU devices**

Shows how to train a model on the forest cover type dataset using GPU acceleration. The forest cover type dataset has 581,012 rows and 54 features, making it time consuming to process. We compare the run-time and accuracy of the GPU and CPU histogram algorithms.

In addition, The demo showcases using GPU with other GPU-related libraries including cupy and cuml. These libraries are not strictly required.

```python
import time
import cupy as cp
from cuml.model_selection import train_test_split
from sklearn.datasets import fetch_covtype
import xgboost as xgb

# Fetch dataset using sklearn
X, y = fetch_covtype(return_X_y=True)
X = cp.array(X)
y = cp.array(y)
y -= y.min()

# Create 0.75/0.25 train/test split
X_train, X_test, y_train, y_test = train_test_split(
    X, y, test_size=0.25, train_size=0.75, random_state=42
)

# Specify sufficient boosting iterations to reach a minimum
num_round = 3000
```

(continues on next page)
# Leave most parameters as default
clf = xgb.XGBClassifier(device="cuda", n_estimators=num_round)

# Train model
start = time.time()
clf.fit(X_train, y_train, eval_set=[[X_test, y_test]])
gpu_res = clf.evals_result()
print("GPU Training Time: \%s seconds" % (str(time.time() - start)))

# Repeat for CPU algorithm
clf = xgb.XGBClassifier(device="cpu", n_estimators=num_round)
start = time.time()
cpu_res = clf.evals_result()
print("CPU Training Time: \%s seconds" % (str(time.time() - start)))

Use GPU to speedup SHAP value computation

Demonstrates using GPU acceleration to compute SHAP values for feature importance.

```python
import shap
from sklearn.datasets import fetch_california_housing
import xgboost as xgb

# Fetch dataset using sklearn
data = fetch_california_housing()
print(data.DESCR)
X = data.data
y = data.target

num_round = 500

param = {
    "eta": 0.05,
    "max_depth": 10,
    "tree_method": "hist",
    "device": "cuda",
}

# GPU accelerated training
dtrain = xgb.DMatrix(X, label=y, feature_names=data.feature_names)
model = xgb.train(param, dtrain, num_round)

# Compute shap values using GPU with xgboost
model.set_param({"device": "cuda"})
shap_values = model.predict(dtrain, pred_contribs=True)

# Compute shap interaction values using GPU
shap_interaction_values = model.predict(dtrain, pred_interactions=True)
```

# shap will call the GPU accelerated version as long as the device parameter is set to
# "cuda"
explainer = shap.TreeExplainer(model)
shap_values = explainer.shap_values(X)

# visualize the first prediction's explanation
shap.force_plot(
    explainer.expected_value,
    shap_values[0, :],
    X[0, :],
    feature_names=data.feature_names,
    matplotlib=True,
)

# Show a summary of feature importance
shap.summary_plot(shap_values, X, plot_type="bar", feature_names=data.feature_names)

Using XGBoost with RAPIDS Memory Manager (RMM) plugin

RAPIDS Memory Manager (RMM) library provides a collection of efficient memory allocators for NVIDIA GPUs. It is now possible to use XGBoost with memory allocators provided by RMM, by enabling the RMM integration plugin.

The demos in this directory highlights one RMM allocator in particular: the pool sub-allocator. This allocator addresses the slow speed of `cudaMalloc()` by allocating a large chunk of memory upfront. Subsequent allocations will draw from the pool of already allocated memory and thus avoid the overhead of calling `cudaMalloc()` directly. See this GTC talk slides for more details.

Before running the demos, ensure that XGBoost is compiled with the RMM plugin enabled. To do this, run CMake with option `-DPLUGIN_RMM=ON` (also required):

```
cmake .. -DUSE_CUDA=ON -DUSE_NCCL=ON -DPLUGIN_RMM=ON
make -j$(nproc)
```

CMake will attempt to locate the RMM library in your build environment. You may choose to build RMM from the source, or install it using the Conda package manager. If CMake cannot find RMM, you should specify the location of RMM with the CMake prefix:

```
# If using Conda:
cmake .. -DUSE_CUDA=ON -DUSE_NCCL=ON -DPLUGIN_RMM=ON -DCMAKE_PREFIX_PATH=$CONDA_PREFIX
# If using RMM installed with a custom location
cmake .. -DUSE_CUDA=ON -DUSE_NCCL=ON -DPLUGIN_RMM=ON -DCMAKE_PREFIX_PATH=/path/to/rmm
```

Informing XGBoost about RMM pool

When XGBoost is compiled with RMM, most of the large size allocation will go through RMM allocators, but some small allocations in performance critical areas are using a different caching allocator so that we can have better control over memory allocation behavior. Users can override this behavior and force the use of rmm for all allocations by setting the global configuration `use_rmm`:

```
with xgb.config_context(use_rmm=True):
cf = xgb.XGBClassifier(tree_method="hist", device="cuda")
```
Depending on the choice of memory pool size and the type of the allocator, this can add more consistency to memory usage but with slightly degraded performance impact.

**No Device Ordinal for Multi-GPU**

Since with RMM the memory pool is pre-allocated on a specific device, changing the CUDA device ordinal in XGBoost can result in memory error `cudaErrorIllegalAddress`. Use the `CUDA_VISIBLE_DEVICES` environment variable instead of the `device="cuda:1"` parameter for selecting device. For distributed training, the distributed computing frameworks like `dask-cuda` are responsible for device management.

**Memory Over-Subscription**

⚠️ **Warning**

This feature is still experimental and is under active development.

The newer NVIDIA platforms like Grace-Hopper use NVLink-C2C, which allows the CPU and GPU to have a coherent memory model. Users can use the `SamHeadroomMemoryResource` in the latest RMM to utilize system memory for storing data. This can help XGBoost utilize memory from the host for GPU computation, but it may reduce performance due to slower CPU memory speed and page migration overhead.

**Using rmm on a single node device**

```python
import rmm
from sklearn.datasets import make_classification

import xgboost as xgb

# Initialize RMM pool allocator
rmm.reinitialize(pool_allocator=True)
# Optionally force XGBoost to use RMM for all GPU memory allocation, see ./README.md
# xgb.set_config(use_rmm=True)
X, y = make_classification(n_samples=10000, n_informative=5, n_classes=3)
dtrain = xgb.DMatrix(X, label=y)

params = {
    "max_depth": 8,
    "eta": 0.01,
    "objective": "multi:softprob",
    "num_class": 3,
    "tree_method": "hist",
    "device": "cuda",
}
# XGBoost will automatically use the RMM pool allocator
bst = xgb.train(params, dtrain, num_boost_round=100, evals=[(dtrain, "train")])
```
import dask
from dask.distributed import Client
from dask_cuda import LocalCUDACluster
from sklearn.datasets import make_classification
import xgboost as xgb

def main(client):
    # Optionally force XGBoost to use RMM for all GPU memory allocation, see ./README.md
    # xgb.set_config(use_rmm=True)
    X, y = make_classification(n_samples=10000, n_informative=5, n_classes=3)
    # In practice one should prefer loading the data with dask collections instead of
    # using 'from_array'.
    X = dask.array.from_array(X)
    y = dask.array.from_array(y)
    dtrain = xgb.dask.DaskDMatrix(client, X, label=y)

    params = {
        "max_depth": 8,
        "eta": 0.01,
        "objective": "multi:softprob",
        "num_class": 3,
        "tree_method": "hist",
        "eval_metric": "merror",
        "device": "cuda",
    }
    output = xgb.dask.train(
        client, params, dtrain, num_boost_round=100, evals=[(dtrain, "train")]
    )
    bst = output["booster"]
    history = output["history"]
    for i, e in enumerate(history["train"]["merror"]):
        print(f"{i} train-merror: {e}"")

if __name__ == "__main__":
    # To use RMM pool allocator with a GPU Dask cluster, just add rmm_pool_size option
    # to LocalCUDACluster constructor.
    with LocalCUDACluster(rmm_pool_size="2GB") as cluster:
        with Client(cluster) as client:
            main(client)
1.11 XGBoost R Package

You have found the XGBoost R Package!

1.11.1 Get Started

• Checkout the Installation Guide contains instructions to install xgboost, and Tutorials for examples on how to use XGBoost for various tasks.
• Read the API documentation.
• Please visit Walk-through Examples.

1.11.2 Tutorials

XGBoost R Tutorial

Introduction

XGBoost is short for eXtreme Gradient Boosting package.

The purpose of this Vignette is to show you how to use XGBoost to build a model and make predictions. It is an efficient and scalable implementation of gradient boosting framework by @friedman2000additive and @friedman2001greedy. Two solvers are included:

• linear model;
• tree learning algorithm.

It supports various objective functions, including regression, classification and ranking. The package is made to be extendible, so that users are also allowed to define their own objective functions easily.

It has been used to win several Kaggle competitions.

It has several features:

• Speed: it can automatically do parallel computation on Windows and Linux, with OpenMP. It is generally over 10 times faster than the classical gbm.
• Input Type: it takes several types of input data:
  – Dense Matrix: R’s dense matrix, i.e. matrix;
  – Sparse Matrix: R’s sparse matrix, i.e. Matrix::dgCMatrix;
• Data File: local data files;
• xgb.DMatrix: its own class (recommended).
• Sparsity: it accepts sparse input for both tree booster and linear booster, and is optimized for sparse input;
• Customization: it supports customized objective functions and evaluation functions.
Installation

GitHub version

For weekly updated version (highly recommended), install from GitHub:

```r
install.packages("drat", repos="https://cran.rstudio.com")
drat:::addRepo("dmlc")
install.packages("xgboost", repos="http://dmlc.ml/drat/", type = "source")
```

Windows users will need to install Rtools first.

CRAN version

The version 0.4-2 is on CRAN, and you can install it by:

```r
install.packages("xgboost")
```

Formerly available versions can be obtained from the CRAN archive

Learning

For the purpose of this tutorial we will load XGBoost package.

```r
require(xgboost)
```

Dataset presentation

In this example, we are aiming to predict whether a mushroom can be eaten or not (like in many tutorials, example data are the same as you will use on in your every day life :-).

Mushroom data is cited from UCI Machine Learning Repository. @Bache+Lichman:2013.

Dataset loading

We will load the agaricus datasets embedded with the package and will link them to variables.

The datasets are already split in:

- **train**: will be used to build the model;
- **test**: will be used to assess the quality of our model.

Why split the dataset in two parts?

In the first part we will build our model. In the second part we will want to test it and assess its quality. Without dividing the dataset we would test the model on the data which the algorithm have already seen.

```r
data(agaricus.train, package='xgboost')
data(agaricus.test, package='xgboost')
train <- agaricus.train
test <- agaricus.test
```
In the real world, it would be up to you to make this division between train and test data. The way to do it is out of scope for this article, however caret package may help.

Each variable is a list containing two things, label and data:

```
str(train)
```

```
## List of 2
## $ data :Formal class 'dgCMatrix' [package "Matrix"] with 6 slots
##   ..@ i   : int [1:143286] 2 6 8 11 18 20 21 24 28 32 ...
##   ..@ p   : int [1:127] 0 369 372 3306 5845 6489 6513 8380 8384 10991 ...
##   ..@ Dim : int [1:2] 6513 126
##   ..@ Dimnames:List of 2
##     ..$ : NULL
##     ..$ : chr [1:126] "cap-shape=bell" "cap-shape=conical" "cap-shape=convex" ...
##   ..@ x   : num [1:143286] 1 1 1 1 1 1 1 1 1 1 ...
##   ..@ factors : list()
## $ label: num [1:6513] 1 0 0 1 0 0 0 1 0 0 ...
```

label is the outcome of our dataset meaning it is the binary classification we will try to predict.

Let’s discover the dimensionality of our datasets.

```
dim(train$data)
```

```
## [1] 6513 126
```

```
dim(test$data)
```

```
## [1] 1611 126
```

This dataset is very small to not make the R package too heavy, however XGBoost is built to manage huge datasets very efficiently.

As seen below, the data are stored in a dgCMatrix which is a sparse matrix and label vector is a numeric vector ((0,1)):

```
class(train$data)[1]
```

```
## [1] "dgCMatrix"
```

```
class(train$label)
```

```
## [1] "numeric"
```
Basic Training using XGBoost

This step is the most critical part of the process for the quality of our model.

Basic training

We are using the train data. As explained above, both data and label are stored in a list.

In a sparse matrix, cells containing 0 are not stored in memory. Therefore, in a dataset mainly made of 0, memory size is reduced. It is very common to have such a dataset.

We will train decision tree model using the following parameters:

- **objective = "binary:logistic"**: we will train a binary classification model;
- **max.depth = 2**: the trees won’t be deep, because our case is very simple;
- **nthread = 2**: the number of CPU threads we are going to use;
- **nrounds = 2**: there will be two passes on the data, the second one will enhance the model by further reducing the difference between ground truth and prediction.

```r
bstSparse <- xgboost(data = train$data, label = train$label, max.depth = 2, eta = 1, nthread = 2, nrounds = 2, objective = "binary:logistic")
```

```
## [0] train-error:0.046522
## [1] train-error:0.022263
```

The more complex the relationship between your features and your label is, the more passes you need.

Parameter variations

Dense matrix

Alternatively, you can put your dataset in a dense matrix, i.e. a basic R matrix.

```r
bstDense <- xgboost(data = as.matrix(train$data), label = train$label, max.depth = 2, eta = 1, nthread = 2, nrounds = 2, objective = "binary:logistic")
```

```
## [0] train-error:0.046522
## [1] train-error:0.022263
```

xgb.DMatrix

XGBoost offers a way to group them in a xgb.DMatrix. You can even add other meta data in it. This will be useful for the most advanced features we will discover later.

```r
dtrain <- xgb.DMatrix(data = train$data, label = train$label)
bstDMatrix <- xgboost(data = dtrain, max.depth = 2, eta = 1, nthread = 2, nrounds = 2, objective = "binary:logistic")
```
## [0] train-error:0.046522
## [1] train-error:0.022263

### Verbose option

**XGBoost** has several features to help you view the learning progress internally. The purpose is to help you to set the best parameters, which is the key of your model quality.

One of the simplest way to see the training progress is to set the `verbose` option (see below for more advanced techniques).

```r
# verbose = 0, no message
bst <- xgboost(data = dtrain, max.depth = 2, eta = 1, nthread = 2, nrounds = 2,
               objective = "binary:logistic", verbose = 0)

# verbose = 1, print evaluation metric
bst <- xgboost(data = dtrain, max.depth = 2, eta = 1, nthread = 2, nrounds = 2,
               objective = "binary:logistic", verbose = 1)

## [0] train-error:0.046522
## [1] train-error:0.022263
```

```r
# verbose = 2, also print information about tree
bst <- xgboost(data = dtrain, max.depth = 2, eta = 1, nthread = 2, nrounds = 2,
               objective = "binary:logistic", verbose = 2)

## [11:41:01] amalgamation/../src/tree/updater_prune.cc:74: tree pruning end, 1 roots, 6
# extra nodes, 0 pruned nodes, max_depth=2
## [0] train-error:0.046522
## [11:41:01] amalgamation/../src/tree/updater_prune.cc:74: tree pruning end, 1 roots, 4
# extra nodes, 0 pruned nodes, max_depth=2
## [1] train-error:0.022263
```

### Basic prediction using XGBoost

**Perform the prediction**

The purpose of the model we have built is to classify new data. As explained before, we will use the `test` dataset for this step.

```r
pred <- predict(bst, test$data)

# size of the prediction vector
print(length(pred))

## [1] 1611
```

```r
# limit display of predictions to the first 10
print(head(pred))
```
These numbers don’t look like binary classification \{0, 1\}. We need to perform a simple transformation before being able to use these results.

**Transform the regression in a binary classification**

The only thing that XGBoost does is a regression. XGBoost is using label vector to build its regression model.

How can we use a regression model to perform a binary classification?

If we think about the meaning of a regression applied to our data, the numbers we get are probabilities that a datum will be classified as 1. Therefore, we will set the rule that if this probability for a specific datum is \(> 0.5\) then the observation is classified as 1 (or 0 otherwise).

```r
prediction <- as.numeric(pred > 0.5)
print(head(prediction))
```

```r
## [1] 0 1 0 0 0 1
```

**Measuring model performance**

To measure the model performance, we will compute a simple metric, the average error.

```r
err <- mean(as.numeric(pred > 0.5) != test$label)
print(paste("test-error= ", err))
```

```r
## [1] "test-error= 0.0217256362507759"
```

Note that the algorithm has not seen the test data during the model construction.

Steps explanation:

1. `as.numeric(pred > 0.5)` applies our rule that when the probability (\(\approx\) regression \(\approx\) prediction) is \(> 0.5\) the observation is classified as 1 and 0 otherwise;
2. `probabilityVectorPreviouslyComputed != test$label` computes the vector of error between true data and computed probabilities;
3. `mean(vectorOfErrors)` computes the average error itself.

The most important thing to remember is that to do a classification, you just do a regression to the label and then apply a threshold.

*Multiclass* classification works in a similar way.

This metric is 0.02 and is pretty low: our yummly mushroom model works well!
**Advanced features**

Most of the features below have been implemented to help you to improve your model by offering a better understanding of its content.

**Dataset preparation**

For the following advanced features, we need to put data in `xgb.DMatrix` as explained above.

```r
dtrain <- xgb.DMatrix(data = train$data, label=train$label)
dtest <- xgb.DMatrix(data = test$data, label=test$label)
```

**Measure learning progress with xgb.train**

Both `xgboost` (simple) and `xgb.train` (advanced) functions train models.

One of the special features of `xgb.train` is the capacity to follow the progress of the learning after each round. Because of the way boosting works, there is a time when having too many rounds lead to overfitting. You can see this feature as a cousin of a cross-validation method. The following techniques will help you to avoid overfitting or optimizing the learning time in stopping it as soon as possible.

One way to measure progress in the learning of a model is to provide to XGBoost a second dataset already classified. Therefore it can learn on the first dataset and test its model on the second one. Some metrics are measured after each round during the learning.

In some way it is similar to what we have done above with the average error. The main difference is that above it was after building the model, and now it is during the construction that we measure errors.

For the purpose of this example, we use `watchlist` parameter. It is a list of `xgb.DMatrix`, each of them tagged with a name.

```r
watchlist <- list(train=dtrain, test=dtest)
bst <- xgb.train(data=dtrain, max.depth=2, eta=1, nthread = 2, nrounds=2, watchlist=watchlist, objective = "binary:logistic")
```

XGBoost has computed at each round the same average error metric seen above (we set `nrounds` to 2, that is why we have two lines). Obviously, the `train-error` number is related to the training dataset (the one the algorithm learns from) and the `test-error` number to the test dataset.

Both training and test error related metrics are very similar, and in some way, it makes sense: what we have learned from the training dataset matches the observations from the test dataset.

If with your own dataset you do not have such results, you should think about how you divided your dataset in training and test. May be there is something to fix. Again, caret package may help.

For a better understanding of the learning progression, you may want to have some specific metric or even use multiple evaluation metrics.

```r
bst <- xgb.train(data=dtrain, max.depth=2, eta=1, nthread = 2, nrounds=2, watchlist=watchlist, eval.metric = "error", eval.metric = "logloss", objective = "binary:logistic")
```
eval.metric allows us to monitor two new metrics for each round, logloss and error.

**Linear boosting**

Until now, all the learnings we have performed were based on boosting trees. **XGBoost** implements a second algorithm, based on linear boosting. The only difference with the previous command is booster = "gblinear" parameter (and removing eta parameter).

```r
bst <- xgb.train(data=dtrain, booster = "gblinear", nthread = 2, nrounds=2,␣
    watchlist=watchlist, eval.metric = "error", eval.metric = "logloss", objective =
    "binary:logistic")
```

In this specific case, **linear boosting** gets slightly better performance metrics than a decision tree based algorithm.

In simple cases, this will happen because there is nothing better than a linear algorithm to catch a linear link. However, decision trees are much better to catch a non linear link between predictors and outcome. Because there is no silver bullet, we advise you to check both algorithms with your own datasets to have an idea of what to use.

**Manipulating xgb.DMatrix**

**Save / Load**

Like saving models, xgb.DMatrix object (which groups both dataset and outcome) can also be saved using xgb.DMatrix.save function.

```r
xgb.DMatrix.save(dtrain, "dtrain.buffer")
```

```r
## [1] TRUE
```

# to load it in, simply call xgb.DMatrix
dtrain2 <- xgb.DMatrix("dtrain.buffer")

```r
## [11:41:01] 6513x126 matrix with 143286 entries loaded from dtrain.buffer
```

bst <- xgb.train(data=dtrain2, max.depth=2, eta=1, nthread = 2, nrounds=2,␣
    watchlist=watchlist, objective = "binary:logistic")

```r
## [0] train-error:0.046522 test-error:0.042831
## [1] train-error:0.022263 test-error:0.021726
```
Information extraction

Information can be extracted from an xgb.DMatrix using getinfo function. Hereafter we will extract label data.

```r
define label = getinfo(dtest, "label")
pred <- predict(bst, dtest)
err <- as.numeric(sum(as.integer(pred > 0.5) != label))/length(label)
print(paste("test-error=", err))
```

View feature importance/influence from the learnt model

Feature importance is similar to R gbm package’s relative influence (rel.inf).

```r
importance_matrix <- xgb.importance(model = bst)
print(importance_matrix)
xgb.plot.importance(importance_matrix = importance_matrix)
```

View the trees from a model

You can dump the tree you learned using xgb.dump into a text file.

```r
xgb.dump(bst, with_stats = TRUE)
```

You can plot the trees from your model using `xgb.plot.tree`:

```r
xgb.plot.tree(model = bst)
```

if you provide a path to `fname` parameter you can save the trees to your hard drive.
Save and load models

Maybe your dataset is big, and it takes time to train a model on it? May be you are not a big fan of losing time in redoing the same task again and again? In these very rare cases, you will want to save your model and load it when required.

Helpfully for you, **XGBoost** implements such functions.

```r
# save model to binary local file
xgb.save(bst, "xgboost.model")
```

```r
## [1] TRUE
```

*xgb.save* function should return TRUE if everything goes well and crashes otherwise.

An interesting test to see how identical our saved model is to the original one would be to compare the two predictions.

```r
# load binary model to R
bst2 <- xgb.load("xgboost.model")
pred2 <- predict(bst2, test$data)

# And now the test
print(paste("sum(abs(pred2-pred))=", sum(abs(pred2-pred))))
```

```r
## [1] "sum(abs(pred2-pred))= 0"
```

result is 0? We are good!

In some very specific cases, like when you want to pilot **XGBoost** from **caret** package, you will want to save the model as a R binary vector. See below how to do it.

```r
# save model to R's raw vector
rawVec <- xgb.save.raw(bst)

# print class
print(class(rawVec))
```

```r
## [1] "raw"
```

```r
# load binary model to R
bst3 <- xgb.load(rawVec)
pred3 <- predict(bst3, test$data)

# pred3 should be identical to pred
print(paste("sum(abs(pred3-pred))=", sum(abs(pred3-pred))))
```

```r
## [1] "sum(abs(pred3-pred))= 0"
```

Again 0? It seems that **XGBoost** works pretty well!
References

Understand your dataset with XGBoost

Introduction

The purpose of this vignette is to show you how to use XGBoost to discover and understand your own dataset better. This vignette is not about predicting anything (see XGBoost presentation). We will explain how to use XGBoost to highlight the link between the features of your data and the outcome.

Package loading:

```r
require(xgboost)
require(Matrix)
require(data.table)
if (!require(‘vcd’)) {
  install.packages(‘vcd’)
}
```

VCD package is used for one of its embedded dataset only.

Preparation of the dataset

Numeric v.s. categorical variables

XGBoost manages only numeric vectors.

What to do when you have categorical data?

A categorical variable has a fixed number of different values. For instance, if a variable called Colour can have only one of these three values, red, blue or green, then Colour is a categorical variable.

In R, a categorical variable is called factor.

Type `factor` in the console for more information.

To answer the question above we will convert categorical variables to numeric ones.

Conversion from categorical to numeric variables

Looking at the raw data

+In this Vignette we will see how to transform a dense data.frame (dense = the majority of the matrix is non-zero) with categorical variables to a very sparse matrix (sparse = lots of zero entries in the matrix) of numeric features.

The method we are going to see is usually called one-hot encoding.

The first step is to load the Arthritis dataset in memory and wrap it with the data.table package.

```r
data(Arthritis)
df <- data.table(Arthritis, keep.rownames = FALSE)
```

Data.table is 100% compliant with R data.frame but its syntax is more consistent and its performance for large dataset is best in class (dplyr from R and Pandas from Python included). Some parts of XGBoost’s R package use data.table.
The first thing we want to do is to have a look to the first few lines of the `data.table`:

```r
head(df)
## ID Treatment Sex Age Improved
## 1: 57 Treated Male 27 Some
## 2: 46 Treated Male 29 None
## 3: 77 Treated Male 30 None
## 4: 17 Treated Male 32 Marked
## 5: 36 Treated Male 46 Marked
## 6: 23 Treated Male 58 Marked
```

Now we will check the format of each column.

```r
str(df)
## Classes 'data.table' and 'data.frame': 84 obs. of 5 variables:
## $ ID     : int 57 46 77 17 36 23 75 39 33 55 ...
## $ Treatment: Factor w/ 2 levels "Placebo","Treated": 2 2 2 2 2 2 2 2 2 2 ...
## $ Sex    : Factor w/ 2 levels "Female","Male": 2 2 2 2 2 2 2 2 2 2 ...
## $ Age    : int 27 29 30 32 46 58 59 59 63 63 ...
## $ Improved: Ord.factor w/ 3 levels "None"<"Some"<..: 2 1 1 3 3 3 1 3 1 1 ... 
## - attr(*, ".internal.selfref")=<externalptr>
```

2 columns have `factor` type, one has `ordinal` type.

- `ordinal` variable:
  - can take a limited number of values (like `factor`);
  - these values are ordered (unlike `factor`). Here these ordered values are: Marked > Some > None

**Creation of new features based on old ones**

We will add some new `categorical` features to see if it helps.

**Grouping per 10 years**

For the first features we create groups of age by rounding the real age.

Note that we transform it to `factor` so the algorithm treats these age groups as independent values.

Therefore, 20 is not closer to 30 than 60. In other words, the distance between ages is lost in this transformation.

```r
head(df[, AgeDiscret := as.factor(round(Age / 10, 0))])
## ID Treatment Sex Age Improved AgeDiscret
## 1: 57 Treated Male 27 Some 3
## 2: 46 Treated Male 29 None 3
## 3: 77 Treated Male 30 None 3
## 4: 17 Treated Male 32 Marked 3
## 5: 36 Treated Male 46 Marked 5
## 6: 23 Treated Male 58 Marked 6
```
Randomly split into two groups

The following is an even stronger simplification of the real age with an arbitrary split at 30 years old. I choose this value based on nothing. We will see later if simplifying the information based on arbitrary values is a good strategy (you may already have an idea of how well it will work...).

```r
head(df[, AgeCat := as.factor(ifelse(Age > 30, "Old", "Young"))])
```

<table>

</tbody>
</table>

Risks in adding correlated features

These new features are highly correlated to the Age feature because they are simple transformations of this feature.

For many machine learning algorithms, using correlated features is not a good idea. It may sometimes make prediction less accurate, and most of the time make interpretation of the model almost impossible. GLM, for instance, assumes that the features are uncorrelated.

Fortunately, decision tree algorithms (including boosted trees) are very robust to these features. Therefore we don’t have to do anything to manage this situation.

Cleaning data

We remove ID as there is nothing to learn from this feature (it would just add some noise).

```r
df[, ID := NULL]
```

We will list the different values for the column Treatment:

```r
levels(df[, Treatment])
```

```
# [1] "Placebo" "Treated"
```

Encoding categorical features

Next step, we will transform the categorical data to dummy variables. Several encoding methods exist, e.g., one-hot encoding is a common approach. We will use the dummy contrast coding which is popular because it produces “full rank” encoding (also see this blog post by Max Kuhn).

The purpose is to transform each value of each categorical feature into a binary feature \{0, 1\}.

For example, the column Treatment will be replaced by two columns, TreatmentPlacebo, and TreatmentTreated. Each of them will be binary. Therefore, an observation which has the value Placebo in column Treatment before the transformation will have the value 1 in the new column TreatmentPlacebo and the value 0 in the new column TreatmentTreated after the transformation. The column TreatmentPlacebo will disappear during the contrast encoding, as it would be absorbed into a common constant intercept column.
Column `Improved` is excluded because it will be our label column, the one we want to predict.

```r
code
sparse_matrix <- sparse.model.matrix(Improved ~ ., data = df)[, -1]
head(sparse_matrix)
```

```
## 6 x 9 sparse Matrix of class "dgCMatrix"
##          TreatmentTreated SexMale Age AgeDiscret3 AgeDiscret4 AgeDiscret5 AgeDiscret6
## 1          1            1      27           1           .           .           .
## 2          1            1      29           1           .           .           .
## 3          1            1      30           1           .           .           .
## 4          1            1      32           1           .           .           .
## 5          1            1      46           .           .           1           .
## 6          1            1      58           .           .           .           1
##          AgeDiscret7 AgeCatYoung
## 1           .           1
## 2           .           1
## 3           .           1
## 4           .           .
## 5           .           .
## 6           .           .
```

Formula `Improved ~ .` used above means transform all categorical features but column `Improved` to binary values. The `-1` column selection removes the intercept column which is full of 1 (this column is generated by the conversion). For more information, you can type `?sparse.model.matrix` in the console.

Create the output numeric vector (not as a sparse Matrix):

```r
code
output_vector <- df[, Improved] == "Marked"
```

1. set `Y` vector to 0;
2. set `Y` to 1 for rows where `Improved` == `Marked` is TRUE;
3. return `Y` vector.

**Build the model**

The code below is very usual. For more information, you can look at the documentation of `xgboost` function (or at the vignette XGBoost presentation).

```r
code
bst <- xgboost(data = sparse_matrix, label = output_vector, max_depth = 4, eta = 1, nthread = 2, nrounds = 10, objective = "binary:logistic")
```

```
## [1] train-logloss:0.485466
## [2] train-logloss:0.438534
## [3] train-logloss:0.412250
## [4] train-logloss:0.395828
## [5] train-logloss:0.384264
## [6] train-logloss:0.374028
## [7] train-logloss:0.365005
## [8] train-logloss:0.351233
## [9] train-logloss:0.341678
## [10] train-logloss:0.334465
```
You can see some train-logloss: 0.XXXXX lines followed by a number. It decreases. Each line shows how well the model explains the data. Lower is better.

A small value for training error may be a symptom of overfitting, meaning the model will not accurately predict unseen values.

**Feature importance**

**Measure feature importance**

**Build the feature importance data.table**

Remember, each binary column corresponds to a single value of one of categorical features.

```
importance <- xgb.importance(feature_names = colnames(sparse_matrix), model = bst)
head(importance)
```

<table>
<thead>
<tr>
<th>##</th>
<th>Feature</th>
<th>Gain</th>
<th>Cover</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>#1</td>
<td>Age</td>
<td>0.622031769</td>
<td>0.67251696</td>
<td>0.67241379</td>
</tr>
<tr>
<td>#2</td>
<td>TreatmentTreated</td>
<td>0.285750540</td>
<td>0.11916651</td>
<td>0.10344828</td>
</tr>
<tr>
<td>#3</td>
<td>SexMale</td>
<td>0.048744022</td>
<td>0.04522028</td>
<td>0.08620690</td>
</tr>
<tr>
<td>#4</td>
<td>AgeDiscret6</td>
<td>0.016604639</td>
<td>0.04784639</td>
<td>0.05172414</td>
</tr>
<tr>
<td>#5</td>
<td>AgeDiscret3</td>
<td>0.001637581</td>
<td>0.08028951</td>
<td>0.05172414</td>
</tr>
<tr>
<td>#6</td>
<td>AgeDiscret4</td>
<td>0.009270557</td>
<td>0.02858801</td>
<td>0.01724138</td>
</tr>
</tbody>
</table>
```

The column Gain provides the information we are looking for.

As you can see, features are classified by Gain.

Gain is the improvement in accuracy brought by a feature to the branches it is on. The idea is that before adding a new split on a feature X to the branch there were some wrongly classified elements; after adding the split on this feature, there are two new branches, and each of these branches is more accurate (one branch saying if your observation is on this branch then it should be classified as 1, and the other branch saying the exact opposite).

Cover is related to the second order derivative (or Hessian) of the loss function with respect to a particular variable; thus, a large value indicates a variable has a large potential impact on the loss function and so is important.

Frequency is a simpler way to measure the Gain. It just counts the number of times a feature is used in all generated trees. You should not use it (unless you know why you want to use it).

**Plotting the feature importance**

All these things are nice, but it would be even better to plot the results.

```
xgb.plot.importance(importance_matrix = importance)
```

Running this line of code, you should get a bar chart showing the importance of the 6 features (containing the same data as the output we saw earlier, but displaying it visually for easier consumption). Note that xgb.ggplot.importance is also available for all the ggplot2 fans!

Depending of the dataset and the learning parameters you may have more than two clusters. Default value is to limit them to 10, but you can increase this limit. Look at the function documentation for more information.

According to the plot above, the most important features in this dataset to predict if the treatment will work are:
• An individual’s age;
• Having received a placebo or not;
• Gender;
• Our generated feature AgeDiscret. We can see that its contribution is very low.

**Do these results make sense?**

Let’s check some Chi2 between each of these features and the label.

Higher Chi2 means better correlation.

```r
c2 <- chisq.test(df$Age, output_vector)
print(c2)
```

```r
## Pearson's Chi-squared test
## data: df$Age and output_vector
## X-squared = 35.475, df = 35, p-value = 0.4458
```

The Pearson correlation between Age and illness disappearing is **35.47**.

```r
c2 <- chisq.test(df$AgeDiscret, output_vector)
print(c2)
```

```r
## Pearson's Chi-squared test
## data: df$AgeDiscret and output_vector
## X-squared = 8.2554, df = 5, p-value = 0.1427
```

Our first simplification of Age gives a Pearson correlation of **8.26**.

```r
c2 <- chisq.test(df$AgeCat, output_vector)
print(c2)
```

```r
## Pearson's Chi-squared test with Yates' continuity correction
## data: df$AgeCat and output_vector
## X-squared = 2.3571, df = 1, p-value = 0.1247
```

The perfectly random split we did between young and old at 30 years old has a low correlation of **2.36**. This suggests that, for the particular illness we are studying, the age at which someone is vulnerable to this disease is likely very different from 30.

Moral of the story: don’t let your gut lower the quality of your model.

In *data science*, there is the word *science* :-)
Conclusion

As you can see, in general destroying information by simplifying it won’t improve your model. Chi2 just demonstrates that.

But in more complex cases, creating a new feature from an existing one may help the algorithm and improve the model. The case studied here is not complex enough to show that. Check Kaggle website for some challenging datasets.

Moreover, you can see that even if we have added some new features which are not very useful/highly correlated with other features, the boosting tree algorithm was still able to choose the best one (which in this case is the Age).

Linear models may not perform as well.

Special Note: What about Random Forests™?

As you may know, the Random Forests algorithm is cousin with boosting and both are part of the ensemble learning family.

Both train several decision trees for one dataset. The main difference is that in Random Forests, trees are independent and in boosting, the N+1-st tree focuses its learning on the loss (<= what has not been well modeled by the tree N).

This difference can have an impact on an edge case in feature importance analysis: correlated features.

Imagine two features perfectly correlated, feature A and feature B. For one specific tree, if the algorithm needs one of them, it will choose randomly (true in both boosting and Random Forests). However, in Random Forests this random choice will be done for each tree, because each tree is independent from the others. Therefore, approximately (and depending on your parameters) 50% of the trees will choose feature A and the other 50% will choose feature B. So the importance of the information contained in A and B (which is the same, because they are perfectly correlated) is diluted in A and B. So you won’t easily know this information is important to predict what you want to predict! It is even worse when you have 10 correlated features...

In boosting, when a specific link between feature and outcome have been learned by the algorithm, it will try to not refocus on it (in theory it is what happens, reality is not always that simple). Therefore, all the importance will be on feature A or on feature B (but not both). You will know that one feature has an important role in the link between the observations and the label. It is still up to you to search for the correlated features to the one detected as important if you need to know all of them.

If you want to try Random Forests algorithm, you can tweak XGBoost parameters!

For instance, to compute a model with 1000 trees, with a 0.5 factor on sampling rows and columns:

```r
#Random Forest - 1000 trees
bst <- xgboost(
    data = train$data
    , label = train$label
    , max_depth = 4
    , num_parallel_tree = 1000
    , subsample = 0.5
    , colsample_bytree = 0.5
    , nrounds = 1
    , objective = "binary:logistic"
)
```

(continues on next page)
xgboost, Release 2.1.1

## [1] train-logloss:0.456201

#Boosting - 3 rounds
bst <- xgboost(
    data = train$data
    , label = train$label
    , max_depth = 4
    , nrounds = 3
    , objective = "binary:logistic"
)

## [1] train-logloss:0.444882
## [2] train-logloss:0.302428
## [3] train-logloss:0.212847

Note that the parameter `round` is set to 1.

Random Forests is a trademark of Leo Breiman and Adele Cutler and is licensed exclusively to Salford Systems for the commercial release of the software.

### 1.11.3 Other topics

#### Handling of indexable elements

There are many functionalities in XGBoost which refer to indexable elements in a countable set, such as boosting rounds / iterations / trees in a model (which can be referred to by number), classes, categories / levels in categorical features, among others.

XGBoost, being written in C++, uses base-0 indexing and considers ranges / sequences to be inclusive of the left end but not the right one - for example, a range (0, 3) would include the first three elements, numbered 0, 1, and 2.

The Python interface uses this same logic, since this is also the way that indexing in Python works, but other languages like R have different logic. In R, indexing is base-1 and ranges / sequences are inclusive of both ends - for example, to refer to the first three elements in a sequence, the interval would be written as (1, 3), and the elements numbered 1, 2, and 3.

In order to provide a more idiomatic R interface, XGBoost adjusts its user-facing R interface to follow this and similar R conventions, but internally, it needs to convert all these numbers to the format that the C interface uses. This is made more problematic by the fact that models are meant to be serializable and loadable in other interfaces, which will have different indexing logic.

The following adjustments are made in the R interface:

- Slicing method for DMatrix, which takes an array of integers, is converted to base-0 indexing by subtracting 1 from each element. Note that this is done in the C-level wrapper function for R, unlike all other conversions which are done in R before being passed to C.
- Slicing method for Booster takes a sequence defined by start, end, and step. The R interface is made to work the same way as R’s `seq` from the user’s POV, so it always adjusts the left end by subtracting one, and depending on whether the step size ends exactly or not at the right end, will also adjust the right end to be non-inclusive in C indexing.
- Parameter `iterationrange` in `predict` is also made to behave the same way as R’s `seq`. Since it doesn’t have a step size, just adjusting the left end by subtracting 1 suffices here.
- **best_iteration**, depending on the context, might be stored as both a C-level booster attribute, and as an R attribute. Since the C-level attributes are shared across interfaces and used in prediction methods, in order to improve compatibility, it leaves this C-level attribute in base-0 indexing, but the R attribute, if present, will be adjusted to base-1 indexing. Note that the predict method in R and other interfaces will look at the C-level attribute only.

- Other references to iteration numbers or boosting rounds, such as when printing metrics or saving model snapshots, also follow base-1 indexing. These other references are coded entirely in R, as the C-level functions do not handle such functionalities.

- Terminal leaf / node numbers are returned in base-0 indexing, just like they come from the C interface.

- Tree numbers in plots follow base-1 indexing. Note that these are only displayed when producing these plots through the R interface’s own handling of DiagrammeR objects, but not when using the C-level GraphViz ‘dot’ format generator for plots.

- Feature numbers when producing feature importances, JSONs, trees-to-tables, and SHAP; are all following base-0 indexing.

- Categorical features are defined in R as a factor type which encodes with base-1 indexing. When categorical features are passed as R factor types, the conversion is done automatically to base-0 indexing, but if the user wishes to manually supply categorical features as already-encoded integers, then those integers need to already be in base-0 encoding.

- Categorical levels (categories) in outputs such as plots, JSONs, and trees-to-tables; are also referred to using base-0 indexing, regardless of whether they went into the model as integers or as factor-typed columns.

- Categorical labels for DMatrices do not undergo any extra processing - the user must supply base-0 encoded labels.

- A function to retrieve class-specific coefficients when using the linear coefficients history callback takes a class index parameter, which also does not undergo any conversion (i.e. user must pass a base-0 index), in order to match with the label logic - that is, the same class index will refer to the class encoded with that number in the DMatrix label field.

New additions to the R interface that take on indexable elements should be mindful of these conventions and try to mimic R’s behavior as much as possible.

### 1.12 XGBoost JVM Package

You have found the XGBoost JVM Package!

#### 1.12.1 Installation

Checkout the Installation Guide for how to install the jvm package, or Building from Source on how to build it from the sources.
1.12.2 Contents

Getting Started with XGBoost4J

This tutorial introduces Java API for XGBoost.

Data Interface

Like the XGBoost python module, XGBoost4J uses DMatrix to handle data. LIBSVM txt format file, sparse matrix in CSR/CSC format, and dense matrix are supported.

• The first step is to import DMatrix:

```
import ml.dmlc.xgboost4j.java.DMatrix;
```

• Use DMatrix constructor to load data from a libsvm text format file:

```
DMatrix dmat = new DMatrix("train.svm.txt");
```

• Pass arrays to DMatrix constructor to load from sparse matrix.

Suppose we have a sparse matrix

```
1 0 2 0
4 0 0 3
3 1 2 0
```

We can express the sparse matrix in Compressed Sparse Row (CSR) format:

```
long[] rowHeaders = new long[] {0,2,4,7};
float[] data = new float[] {1f,2f,4f,3f,3f,1f,2f};
int[] colIndex = new int[] {0,2,0,3,0,1,2};
int numColumn = 4;
DMatrix dmat = new DMatrix(rowHeaders, colIndex, data, DMatrix.SparseType.CSR,
˓→numColumn);
```

... or in Compressed Sparse Column (CSC) format:

```
long[] colHeaders = new long[] {0,3,4,6,7};
float[] data = new float[] {1f,4f,3f,1f,2f,2f,3f};
int[] rowIndex = new int[] {0,1,2,2,0,2,1};
int numRow = 3;
DMatrix dmat = new DMatrix(colHeaders, rowIndex, data, DMatrix.SparseType.CSC,
˓→numRow);
```

• You may also load your data from a dense matrix. Let’s assume we have a matrix of form

```
1 2
3 4
5 6
```

Using row-major layout, we specify the dense matrix as follows:
float[] data = new float[] {1f, 2f, 3f, 4f, 5f, 6f};
int nrow = 3;
int ncol = 2;
float missing = 0.0f;
DMatrix dmat = new DMatrix(data, nrow, ncol, missing);

• To set weight:

float[] weights = new float[] {1f, 2f, 1f};
dmat.setWeight(weights);

Setting Parameters

To set parameters, parameters are specified as a Map:

Map<String, Object> params = new HashMap<String, Object>() {
    {put("eta", 1.0);
    put("max_depth", 2);
    put("objective", "binary:logistic");
    put("eval_metric", "logloss");
    }};

Training Model

With parameters and data, you are able to train a booster model.

• Import Booster and XGBoost:

import ml.dmlc.xgboost4j.java.Booster;
import ml.dmlc.xgboost4j.java.XGBoost;

• Training

DMatrix trainMat = new DMatrix("train.svm.txt");
DMatrix validMat = new DMatrix("valid.svm.txt");
// Specify a watch list to see model accuracy on data sets
Map<String, DMatrix> watches = new HashMap<String, DMatrix>() {
    {put("train", trainMat);
    put("test", testMat);
    }};
int nround = 2;
Booster booster = XGBoost.train(trainMat, params, nround, watches, null, null);

• Saving model

After training, you can save model and dump it out.
booster.saveModel("model.bin");

- Generating model dump with feature map

```java
// dump without feature map
String[] model_dump = booster.getModelDump(null, false);

// dump with feature map
String[] model_dump_with_feature_map = booster.getModelDump("featureMap.txt", false);
```

- Load a model

```java
Booster booster = XGBoost.loadModel("model.bin");
```

**Prediction**

After training and loading a model, you can use it to make prediction for other data. The result will be a two-dimension float array (nsample, nclass): for `predictLeaf()`, the result would be of shape (nsample, nclass*ntrees).

```java
DMatrix dtest = new DMatrix("test.svm.txt");

// predict
float[][] predicts = booster.predict(dtest);

// predict leaf
float[][] leafPredicts = booster.predictLeaf(dtest, 0);
```

**XGBoost4J-Spark Tutorial (version 0.9+)**

XGBoost4J-Spark is a project aiming to seamlessly integrate XGBoost and Apache Spark by fitting XGBoost to Apache Spark’s MLLIB framework. With the integration, user can not only uses the high-performant algorithm implementation of XGBoost, but also leverages the powerful data processing engine of Spark for:

- Feature Engineering: feature extraction, transformation, dimensionality reduction, and selection, etc.
- Pipelines: constructing, evaluating, and tuning ML Pipelines
- Persistence: persist and load machine learning models and even whole Pipelines

This tutorial is to cover the end-to-end process to build a machine learning pipeline with XGBoost4J-Spark. We will discuss

- Using Spark to preprocess data to fit to XGBoost/XGBoost4J-Spark’s data interface
- Training a XGBoost model with XGBoost4J-Spark
- Serving XGBoost model (prediction) with Spark
- Building a Machine Learning Pipeline with XGBoost4J-Spark
- Running XGBoost4J-Spark in Production

- Build an ML Application with XGBoost4J-Spark
  - Refer to XGBoost4J-Spark Dependency
  - Data Preparation
* Read Dataset with Spark’s Built-In Reader
  * Transform Raw Iris Dataset
    - Dealing with missing values
  - Training
    * Early Stopping
    * Training with Evaluation Sets
  - Prediction
    * Batch Prediction
    * Single instance prediction
  - Model Persistence
    * Model and pipeline persistence
    * Interact with Other Bindings of XGBoost
* Building a ML Pipeline with XGBoost4J-Spark
  - Basic ML Pipeline
  - Pipeline with Hyper-parameter Tuning
* Run XGBoost4J-Spark in Production
  - Parallel/Distributed Training
  - Gang Scheduling
  - Checkpoint During Training

Build an ML Application with XGBoost4J-Spark

Refer to XGBoost4J-Spark Dependency

Before we go into the tour of how to use XGBoost4J-Spark, you should first consult Installation from Maven repository in order to add XGBoost4J-Spark as a dependency for your project. We provide both stable releases and snapshots.

Note

XGBoost4J-Spark requires Apache Spark 2.4+

XGBoost4J-Spark now requires Apache Spark 2.4+. Latest versions of XGBoost4J-Spark uses facilities of org.apache.spark.ml.param.shared extensively to provide for a tight integration with Spark MLLIB framework, and these facilities are not fully available on earlier versions of Spark.

Also, make sure to install Spark directly from Apache website. Upstream XGBoost is not guaranteed to work with third-party distributions of Spark, such as Cloudera Spark. Consult appropriate third parties to obtain their distribution of XGBoost.

Installation from maven repo
Data Preparation

As aforementioned, XGBoost4J-Spark seamlessly integrates Spark and XGBoost. The integration enables users to apply various types of transformation over the training/test datasets with the convenient and powerful data processing framework, Spark.

In this section, we use Iris dataset as an example to showcase how we use Spark to transform raw dataset and make it fit to the data interface of XGBoost.

Iris dataset is shipped in CSV format. Each instance contains 4 features, “sepal length”, “sepal width”, “petal length” and “petal width”. In addition, it contains the “class” column, which is essentially the label with three possible values: “Iris Setosa”, “Iris Versicolour” and “Iris Virginica”.

Read Dataset with Spark’s Built-In Reader

The first thing in data transformation is to load the dataset as Spark’s structured data abstraction, DataFrame.

```java
import org.apache.spark.sql.SparkSession
import org.apache.spark.sql.types.(DoubleType, StringType, StructField, StructType)

val spark = SparkSession.builder().getOrCreate()
val schema = new StructType(Array(
  StructField("sepal length", DoubleType, true),
  StructField("sepal width", DoubleType, true),
  StructField("petal length", DoubleType, true),
  StructField("petal width", DoubleType, true),
  StructField("class", StringType, true)))
val rawInput = spark.read.schema(schema).csv("input_path")
```

At the first line, we create a instance of SparkSession which is the entry of any Spark program working with DataFrame. The schema variable defines the schema of DataFrame wrapping Iris data. With this explicitly set schema, we can define the columns’ name as well as their types; otherwise the column name would be the default ones derived by Spark, such as _col10, etc. Finally, we can use Spark’s built-in csv reader to load Iris csv file as a DataFrame named rawInput.

Spark also contains many built-in readers for other format. The latest version of Spark supports CSV, JSON, Parquet, and LIBSVM.
Transform Raw Iris Dataset

To make Iris dataset be recognizable to XGBoost, we need to

1. Transform String-typed label, i.e. “class”, to Double-typed label.
2. Assemble the feature columns as a vector to fit to the data interface of Spark ML framework.

To convert String-typed label to Double, we can use Spark’s built-in feature transformer `StringIndexer`.

```scala
import org.apache.spark.ml.feature.StringIndexer
val stringIndexer = new StringIndexer()
  .setInputCol("class")
  .setOutputCol("classIndex")
  .fit(rawInput)
val labelTransformed = stringIndexer.transform(rawInput).drop("class")
```

With a newly created StringIndexer instance:

1. we set input column, i.e. the column containing String-typed label
2. we set output column, i.e. the column to contain the Double-typed label.
3. Then we fit StringIndex with our input DataFrame `rawInput`, so that Spark internals can get information like total number of distinct values, etc.

Now we have a StringIndexer which is ready to be applied to our input DataFrame. To execute the transformation logic of StringIndexer, we transform the input DataFrame `rawInput` and to keep a concise DataFrame, we drop the column “class” and only keeps the feature columns and the transformed Double-typed label column (in the last line of the above code snippet).

The `fit` and `transform` are two key operations in MLlib. Basically, `fit` produces a “transformer”, e.g. `StringIndexer`, and each transformer applies `transform` method on DataFrame to add new column(s) containing transformed features/labels or prediction results, etc. To understand more about `fit` and `transform`, You can find more details in here.

Similarly, we can use another transformer, `VectorAssembler`, to assemble feature columns “sepal length”, “sepal width”, “petal length” and “petal width” as a vector.

```scala
import org.apache.spark.ml.feature.VectorAssembler
val vectorAssembler = new VectorAssembler()
  .setInputCols(Array("sepal length", "sepal width", "petal length", "petal width"))
  .setOutputCol("features")
val xgbInput = vectorAssembler.transform(labelTransformed).select("features", "classIndex...
```

Now, we have a DataFrame containing only two columns, “features” which contains vector-represented “sepal length”, “sepal width”, “petal length” and “petal width” and “classIndex” which has Double-typed labels. A DataFrame like this (containing vector-represented features and numeric labels) can be fed to XGBoost4J-Spark’s training engine directly.

---

**Note**

There is no need to assemble feature columns from version 1.6.1+. Instead, users can specify an array of feature column names by setFeaturesCol(value: Array[String]) and XGBoost4j-Spark will do it.
Dealing with missing values

XGBoost supports missing values by default (as described here). If given a SparseVector, XGBoost will treat any values absent from the SparseVector as missing. You are also able to specify to XGBoost to treat a specific value in your Dataset as if it was a missing value. By default XGBoost will treat NaN as the value representing missing.

Example of setting a missing value (e.g. -999) to the “missing” parameter in XGBoostClassifier:

```scala
import ml.dmlc.xgboost4j.scala.spark.XGBoostClassifier
val xgbParam = Map("eta" -> 0.1f,
   "missing" -> -999,
   "objective" -> "multi:softprob",
   "num_class" -> 3,
   "num_round" -> 100,
   "num_workers" -> 2)
val xgbClassifier = new XGBoostClassifier(xgbParam).
   setFeaturesCol("features").
   setLabelCol("classIndex")
```

### Note

Missing values with Spark’s VectorAssembler

If given a Dataset with enough features having a value of 0 Spark’s VectorAssembler transformer class will return a SparseVector where the absent values are meant to indicate a value of 0. This conflicts with XGBoost’s default to treat values absent from the SparseVector as missing. The model would effectively be treating 0 as missing but not declaring that to be so which can lead to confusion when using the trained model on other platforms. To avoid this, XGBoost will raise an exception if it receives a SparseVector and the “missing” parameter has not been explicitly set to 0. To workaround this issue the user has three options:

1. Explicitly convert the Vector returned from VectorAssembler to a DenseVector to return the zeros to the dataset. If doing this with missing values encoded as NaN, you will want to set setHandleInvalid = "keep" on VectorAssembler in order to keep the NaN values in the dataset. You would then set the “missing” parameter to whatever you want to be treated as missing. However this may cause a large amount of memory use if your dataset is very sparse. For example:

```scala
val assembler = new VectorAssembler().setInputCols(feature_names.toArray).
   setOutputCol("features").setHandleInvalid("keep")
// conversion to dense vector using Array()
val featurePipeline = new Pipeline().setStages(Array(assembler))
val featureModel = featurePipeline.fit(df_training)
val featureDf = featureModel.transform(df_training)
val xgbParam = Map("eta" -> 0.1f,
   "max_depth" -> 2, "objective" -> "multi:softprob", "num_class" -> 3, "num_round" -> 100, "num_workers" -> 2,
   "allow_non_zero_for_missing" -> "true", "missing" -> -999)
val xgb = new XGBoostClassifier(xgbParam)
val xgbClassifier = xgb.fit(featureDf)
```

2. Before calling VectorAssembler you can transform the values you want to represent missing into an irregular value that is not 0, NaN, or Null and set the “missing” parameter to 0. The irregular value should ideally be chosen to be outside the range of values that your features have.

3. Do not use the VectorAssembler class and instead use a custom way of constructing a SparseVector that allows for specifying sparsity to indicate a non-zero value. You can then set the “missing” parameter to whatever sparsity indicates in your Dataset. If this approach is taken you can pass the parameter
"allow_non_zero_for_missing_value" -> true to bypass XGBoost’s assertion that “missing” must be zero when given a SparseVector.

Option 1 is recommended if memory constraints are not an issue. Option 3 requires more work to get set up but is guaranteed to give you correct results while option 2 will be quicker to set up but may be difficult to find a good irregular value that does not conflict with your feature values.

**Note**

Using a non-default missing value when using other bindings of XGBoost.

When XGBoost is saved in native format only the booster itself is saved, the value of the missing parameter is not saved alongside the model. Thus, if a non-default missing parameter is used to train the model in Spark the user should take care to use the same missing parameter when using the saved model in another binding.

**Training**

XGBoost supports both regression and classification. While we use Iris dataset in this tutorial to show how we use XGBoost/XGBoost4J-Spark to resolve a multi-classes classification problem, the usage in Regression is very similar to classification.

To train a XGBoost model for classification, we need to claim a XGBoostClassifier first:

```scala
import ml.dmlc.xgboost4j.scala.spark.XGBoostClassifier
val xgbParam = Map("eta" -> 0.1f,
    "max_depth" -> 2,
    "objective" -> "multi:softprob",
    "num_class" -> 3,
    "num_round" -> 100,
    "num_workers" -> 2)
val xgbClassifier = new XGBoostClassifier(xgbParam).
    setFeaturesCol("features").
    setLabelCol("classIndex")
```

The available parameters for training a XGBoost model can be found in [here](#). In XGBoost4J-Spark, we support not only the default set of parameters but also the camel-case variant of these parameters to keep consistent with Spark’s MLLIB parameters.

Specifically, each parameter in this page has its equivalent form in XGBoost4J-Spark with camel case. For example, to set max_depth for each tree, you can pass parameter just like what we did in the above code snippet (as `max_depth` wrapped in a Map), or you can do it through setters in XGBoostClassifer:

```scala
val xgbClassifier = new XGBoostClassifier().
    setFeaturesCol("features").
    setLabelCol("classIndex")
xgbClassifier.setMaxDepth(2)
```

After we set XGBoostClassifier parameters and feature/label column, we can build a transformer, XGBoostClassificationModel by fitting XGBoostClassifier with the input DataFrame. This fit operation is essentially the training process and the generated model can then be used in prediction.

```scala
val xgbClassificationModel = xgbClassifier.fit(xgbInput)
```
Early Stopping

Early stopping is a feature to prevent the unnecessary training iterations. By specifying num_early_stopping_rounds or directly call setNumEarlyStoppingRounds over a XGBoostClassifier or XGBoostRegressor, we can define number of rounds if the evaluation metric going away from the best iteration and early stop training iterations.

When it comes to custom eval metrics, in additonal to num_early_stopping_rounds, you also need to define maximize_evaluation_metrics or call setMaximizeEvaluationMetrics to specify whether you want to maximize or minimize the metrics in training. For built-in eval metrics, XGBoost4J-Spark will automatically select the direction.

For example, we need to maximize the evaluation metrics (set maximize_evaluation_metrics with true), and set num_early_stopping_rounds with 5. The evaluation metric of 10th iteration is the maximum one until now. In the following iterations, if there is no evaluation metric greater than the 10th iteration’s (best one), the training would be early stopped at 15th iteration.

Training with Evaluation Sets

You can also monitor the performance of the model during training with multiple evaluation datasets. By specifying eval_sets or call setEvalSets over a XGBoostClassifier or XGBoostRegressor, you can pass in multiple evaluation datasets typed as a Map from String to DataFrame.

Prediction

XGBoost4J-Spark supports two ways for model serving: batch prediction and single instance prediction.

Batch Prediction

When we get a model, either XGBoostClassificationModel or XGBoostRegressionModel, it takes a DataFrame, read the column containing feature vectors, predict for each feature vector, and output a new DataFrame with the following columns by default:

- XGBoostClassificationModel will output margins (rawPredictionCol), probabilities(probabilityCol) and the eventual prediction labels (predictionCol) for each possible label.
- XGBoostRegressionModel will output prediction label(predictionCol).

Batch prediction expects the user to pass the testset in the form of a DataFrame. XGBoost4J-Spark starts a XGBoost worker for each partition of DataFrame for parallel prediction and generates prediction results for the whole DataFrame in a batch.

```scala
val xgbClassificationModel = xgbClassifier.fit(xgbInput)
val results = xgbClassificationModel.transform(testSet)
```

With the above code snippet, we get a result DataFrame, result containing margin, probability for each class and the prediction for each instance:

<table>
<thead>
<tr>
<th>features</th>
<th>classIndex</th>
<th>rawPrediction</th>
<th>probability</th>
<th>prediction</th>
</tr>
</thead>
<tbody>
<tr>
<td>[5.1,3.5,1.4,0.2]</td>
<td>0.0</td>
<td>[3.45569849014282...</td>
<td>[0.99579632282257...</td>
<td>0.0</td>
</tr>
<tr>
<td>[4.9,3.0,1.4,0.2]</td>
<td>0.0</td>
<td>[3.45569849014282...</td>
<td>[0.99618089199066...</td>
<td>0.0</td>
</tr>
</tbody>
</table>

(continues on next page)
### Single instance prediction

XGBoostClassificationModel or XGBoostRegressionModel support make prediction on single instance as well. It accepts a single Vector as feature, and output the prediction label.

However, the overhead of single-instance prediction is high due to the internal overhead of XGBoost, use it carefully!

```scala
val features = xgbInput.head().getAs[Vector]("features")
val result = xgbClassificationModel.predict(features)
```

### Model Persistence

#### Model and pipeline persistence

A data scientist produces an ML model and hands it over to an engineering team for deployment in a production environment. Reversely, a trained model may be used by data scientists, for example as a baseline, across the process of data exploration. So it’s important to support model persistence to make the models available across usage scenarios and programming languages.

XGBoost4j-Spark supports saving and loading XGBoostClassifier/XGBoostClassificationModel and XGBoostRegressor/XGBoostRegressionModel. It also supports saving and loading a ML pipeline which includes these estimators and models.

We can save the XGBoostClassificationModel to file system:

```scala
val xgbClassificationModelPath = "/tmp/xgbClassificationModel"
xgbClassificationModel.write.overwrite().save(xgbClassificationModelPath)
```

and then loading the model in another session:
Note

Besides dumping the model to raw format, users are able to dump the model to be JSON or UBJ format from version 1.7.0+

```scala
val xgbClassificationModelPath = "~/tmp/xgbClassificationModel"
xgbClassificationModel.write.overwrite().option("format", "json").save(xgbClassificationModelPath)
```

With regards to ML pipeline save and load, please refer the next section.

Interact with Other Bindings of XGBoost

After we train a model with XGBoost4j-Spark on massive dataset, sometimes we want to do model serving in single machine or integrate it with other single node libraries for further processing.

After saving the model, we can load this model with single node Python XGBoost directly from version 1.7.0+

```python
import xgboost as xgb
bst = xgb.Booster({'nthread': 4})
bst.load_model("~/tmp/xgbClassificationModel/data/XGBoostClassificationModel")
```

Before version 1.7.0, XGBoost4j-Spark needs to export model to local manually by:

```scala
val nativeModelPath = "~/tmp/nativeModel"
xgbClassificationModel.nativeBooster.saveModel(nativeModelPath)
```

Then we can load this model with single node Python XGBoost:

```python
import xgboost as xgb
bst = xgb.Booster({'nthread': 4})
bst.load_model(nativeModelPath)
```

Note

Consistency issue between XGBoost4J-Spark and other bindings

There is a consistency issue between XGBoost4J-Spark and other language bindings of XGBoost.

When users use Spark to load training/test data in LIBSVM format with the following code snippet:

```scala
spark.read.format("libsvm").load("trainingset_libsvm")
```

Spark assumes that the dataset is using 1-based indexing (feature indices staring with 1). However, when you do prediction with other bindings of XGBoost (e.g. Python API of XGBoost), XGBoost assumes that the dataset uses 0-based indexing.
is using 0-based indexing (feature indices starting with 0) by default. It creates a pitfall for the users who train model with Spark but predict with the dataset in the same format in other bindings of XGBoost. The solution is to transform the dataset to 0-based indexing before you predict with, for example, Python API, or you append \?indexing_mode=1 to your file path when loading with DMatrix. For example in Python:

```
xgb.DMatrix('test.libsvm?indexing_mode=1')
```

Building a ML Pipeline with XGBoost4J-Spark

Basic ML Pipeline

Spark ML pipeline can combine multiple algorithms or functions into a single pipeline. It covers from feature extraction, transformation, selection to model training and prediction. XGBoost4J-Spark makes it feasible to embed XGBoost into such a pipeline seamlessly. The following example shows how to build such a pipeline consisting of Spark MLlib feature transformer and XGBoostClassifier estimator.

We still use Iris dataset and the `rawInput` DataFrame. First we need to split the dataset into training and test dataset.

```
val Array(training, test) = rawInput.randomSplit(Array(0.8, 0.2), 123)
```

The we build the ML pipeline which includes 4 stages:

- Assemble all features into a single vector column.
- From string label to indexed double label.
- Use XGBoostClassifier to train classification model.
- Convert indexed double label back to original string label.

We have shown the first three steps in the earlier sections, and the last step is finished with a new transformer `IndexToString`:

```
val labelConverter = new IndexToString()
  .setInputCol("prediction")
  .setOutputCol("realLabel")
  .setLabels(stringIndexer.labels)
```

We need to organize these steps as a Pipeline in Spark ML framework and evaluate the whole pipeline to get a PipelineModel:

```
import org.apache.spark.ml.feature._
import org.apache.spark.ml.Pipeline

val pipeline = new Pipeline()
  .setStages(Array(assembler, stringIndexer, booster, labelConverter))
val model = pipeline.fit(training)
```

After we get the PipelineModel, we can make prediction on the test dataset and evaluate the model accuracy.

```
import org.apache.spark.ml.evaluation.MulticlassClassificationEvaluator

val prediction = model.transform(test)
val evaluator = new MulticlassClassificationEvaluator()
val accuracy = evaluator.evaluate(prediction)
```
Pipeline with Hyper-parameter Tuning

The most critical operation to maximize the power of XGBoost is to select the optimal parameters for the model. Tuning parameters manually is a tedious and labor-consuming process. With the latest version of XGBoost4J-Spark, we can utilize the Spark model selecting tool to automate this process.

The following example shows the code snippet utilizing CrossValidation and MulticlassClassificationEvaluator to search the optimal combination of two XGBoost parameters, max_depth and eta. (See XGBoost Parameters.) The model producing the maximum accuracy defined by MulticlassClassificationEvaluator is selected and used to generate the prediction for the test set.

```scala
import org.apache.spark.ml.tuning._
import org.apache.spark.ml.PipelineModel
import ml.dmlc.xgboost4j.scala.spark.XGBoostClassificationModel

val paramGrid = new ParamGridBuilder()
  .addGrid(booster.maxDepth, Array(3, 8))
  .addGrid(booster.eta, Array(0.2, 0.6))
  .build()

val cv = new CrossValidator()
  .setEstimator(pipeline)
  .setEvaluator(evaluator)
  .setEstimatorParamMaps(paramGrid)
  .setNumFolds(3)

val cvModel = cv.fit(training)
val bestModel = cvModel.bestModel.
 asInstanceOf[PipelineModel].stages(2)
  .asInstanceOf[XGBoostClassificationModel]
bestModel.extractParamMap()
```

Run XGBoost4J-Spark in Production

XGBoost4J-Spark is one of the most important steps to bring XGBoost to production environment easier. In this section, we introduce three key features to run XGBoost4J-Spark in production.

Parallel/Distributed Training

The massive size of training dataset is one of the most significant characteristics in production environment. To ensure that training in XGBoost scales with the data size, XGBoost4J-Spark bridges the distributed/parallel processing framework of Spark and the parallel/distributed training mechanism of XGBoost.

In XGBoost4J-Spark, each XGBoost worker is wrapped by a Spark task and the training dataset in Spark’s memory space is fed to XGBoost workers in a transparent approach to the user.

In the code snippet where we build XGBoostClassifier, we set parameter num_workers (or numWorkers). This parameter controls how many parallel workers we want to have when training a XGBoostClassificationModel.

⚠️ Note

Regarding OpenMP optimization
By default, we allocate a core per each XGBoost worker. Therefore, the OpenMP optimization within each XGBoost worker does not take effect and the parallelization of training is achieved by running multiple workers (i.e. Spark tasks) at the same time.

If you do want OpenMP optimization, you have to

1. set `nthread` to a value larger than 1 when creating `XGBoostClassifier/XGBoostRegressor`
2. set `spark.task.cpus` in Spark to the same value as `nthread`

### Gang Scheduling

XGBoost uses `AllReduce` algorithm to synchronize the stats, e.g. histogram values, of each worker during training. Therefore XGBoost4J-Spark requires that all of `nthread * numWorkers` cores should be available before the training runs.

In the production environment where many users share the same cluster, it’s hard to guarantee that your XGBoost4J-Spark application can get all requested resources for every run. By default, the communication layer in XGBoost will block the whole application when it requires more resources to be available. This process usually brings unnecessary resource waste as it keeps the ready resources and try to claim more. Additionally, this usually happens silently and does not bring the attention of users.

XGBoost4J-Spark allows the user to setup a timeout threshold for claiming resources from the cluster. If the application cannot get enough resources within this time period, the application would fail instead of wasting resources for hanging long. To enable this feature, you can set with `XGBoostClassifier/XGBoostRegressor`:

```java
xgbClassifier.setTimeoutRequestWorkers(60000L)
```

or pass in `timeout_request_workers` in `xgbParamMap` when building `XGBoostClassifier`:

```scala
val xgbParam = Map(
  "eta" -> 0.1f,
  "max_depth" -> 2,
  "objective" -> "multi:softprob",
  "num_class" -> 3,
  "num_round" -> 100,
  "num_workers" -> 2,
  "timeout_request_workers" -> 60000L)
val xgbClassifier = new XGBoostClassifier(xgbParam).
  setFeaturesCol("features").
  setLabelCol("classIndex")
```

If XGBoost4J-Spark cannot get enough resources for running two XGBoost workers, the application would fail. Users can have external mechanism to monitor the status of application and get notified for such case.

### Checkpoint During Training

Transient failures are also commonly seen in production environment. To simplify the design of XGBoost, we stop training if any of the distributed workers fail. However, if the training fails after having been through a long time, it would be a great waste of resources.

We support creating checkpoint during training to facilitate more efficient recovery from failure. To enable this feature, you can set how many iterations we build each checkpoint with `setCheckpointInterval` and the location of checkpoints with `setCheckpointPath`:
xgboost, Release 2.1.1

```scala
xgbClassifier.setCheckpointInterval(2)
xgbClassifier.setCheckpointPath("/checkpoint_path")
```

An equivalent way is to pass in parameters in XGBoostClassifier’s constructor:

```scala
val xgbParam = Map("eta" -> 0.1f,
                  "max_depth" -> 2,
                  "objective" -> "multi:softprob",
                  "num_class" -> 3,
                  "num_round" -> 100,
                  "num_workers" -> 2,
                  "checkpoint_path" -> "/checkpoints_path",
                  "checkpoint_interval" -> 2)
val xgbClassifier = new XGBoostClassifier(xgbParam).
                  setFeaturesCol("features").
                  setLabelCol("classIndex")
```

If the training failed during these 100 rounds, the next run of training would start by reading the latest checkpoint file in /checkpoints_path and start from the iteration when the checkpoint was built until the next failure or the specified 100 rounds.

**XGBoost4J-Spark-GPU Tutorial (version 1.6.1+)**

**XGBoost4J-Spark-GPU** is an open source library aiming to accelerate distributed XGBoost training on Apache Spark cluster from end to end with GPUs by leveraging the RAPIDS Accelerator for Apache Spark product.

This tutorial will show you how to use XGBoost4J-Spark-GPU.

- **Build an ML Application with XGBoost4J-Spark-GPU**
  - Add XGBoost to Your Project
  - Data Preparation
    - Read Dataset with Spark’s Built-In Reader
    - Transform Raw Iris Dataset
  - Training
  - Prediction
- **Submit the application**

**Build an ML Application with XGBoost4J-Spark-GPU**

**Add XGBoost to Your Project**

Prior to delving into the tutorial on utilizing XGBoost4J-Spark-GPU, it is advisable to refer to Installation from Maven repository for instructions on adding XGBoost4J-Spark-GPU as a project dependency. We offer both stable releases and snapshots for your convenience.
Data Preparation

In this section, we use the Iris dataset as an example to showcase how we use Apache Spark to transform a raw dataset and make it fit the data interface of XGBoost.

The Iris dataset is shipped in CSV format. Each instance contains 4 features, “sepal length”, “sepal width”, “petal length” and “petal width”. In addition, it contains the “class” column, which is essentially the label with three possible values: “Iris Setosa”, “Iris Versicolour” and “Iris Virginica”.

Read Dataset with Spark’s Built-In Reader

```scala
import org.apache.spark.sql.SparkSession
import org.apache.spark.sql.types.{DoubleType, StringType, StructField, StructType}

val spark = SparkSession.builder().getOrCreate()
val labelName = "class"
val schema = new StructType(
  Array(StructField("sepal length", DoubleType, true),
         StructField("sepal width", DoubleType, true),
         StructField("petal length", DoubleType, true),
         StructField("petal width", DoubleType, true),
         StructField(labelName, StringType, true))
)
val xgbInput = spark.read.option("header", "false")
  .schema(schema)
  .csv(dataPath)
```

At first, we create an instance of a SparkSession which is the entry point of any Spark application working with DataFrames. The `schema` variable defines the schema of the DataFrame wrapping Iris data. With this explicitly set schema, we can define the column names as well as their types; otherwise the column names would be the default ones derived by Spark, such as `_col0`, etc. Finally, we can use Spark’s built-in CSV reader to load the Iris CSV file as a DataFrame named `xgbInput`.

Apache Spark also contains many built-in readers for other formats such as ORC, Parquet, Avro, JSON.

Transform Raw Iris Dataset

To make the Iris dataset recognizable to XGBoost, we need to encode the String-typed label, i.e. “class”, to the Double-typed label.

One way to convert the String-typed label to Double is to use Spark’s built-in feature transformer `StringIndexer`. But this feature is not accelerated in RAPIDS Accelerator, which means it will fall back to CPU. Instead, we use an alternative way to achieve the same goal with the following code:

```scala
import org.apache.spark.sql.expressions.Window
import org.apache.spark.sql.functions._

val spec = Window.orderBy(labelName)
val Array(train, test) = xgbInput
  .withColumn("tmpClassName", dense_rank().over(spec) - 1)
  .drop(labelName)
```

(continues on next page)
With window operations, we have mapped the string column of labels to label indices.

**Training**

The GPU version of XGBoost-Spark supports both regression and classification models. Although we use the Iris dataset in this tutorial to show how we use XGBoost/XGBoost4J-Spark-GPU to resolve a multi-classes classification problem, the usage in Regression is very similar to classification.

To train a XGBoost model for classification, we need to define a XGBoostClassifier first:

```scala
import ml.dmlc.xgboost4j.scala.spark.XGBoostClassifier
val xgbParam = Map(
  "objective" -> "multi:softprob",
  "num_class" -> 3,
  "num_round" -> 100,
  "device" -> "cuda",
  "num_workers" -> 1)
val featuresNames = schema.fieldNames.filter(name => name != labelName)
val xgbClassifier = new XGBoostClassifier(xgbParam)
  .setFeaturesCol(featuresNames)
  .setLabelCol(labelName)
```

The device parameter is for informing XGBoost that CUDA devices should be used instead of CPU. Unlike the single-node mode, GPUs are managed by spark instead of by XGBoost. Therefore, explicitly specified device ordinal like cuda:1 is not support.

The available parameters for training a XGBoost model can be found in [here](#). Similar to the XGBoost4J-Spark package, in addition to the default set of parameters, XGBoost4J-Spark-GPU also supports the camel-case variant of these parameters to be consistent with Spark’s MLlib naming convention.

Specifically, each parameter in this page has its equivalent form in XGBoost4J-Spark-GPU with camel case. For example, to set `max_depth` for each tree, you can pass parameter just like what we did in the above code snippet (as `max_depth` wrapped in a Map), or you can do it through setters in XGBoostClassifier:

```scala
val xgbClassifier = new XGBoostClassifier(xgbParam)
  .setFeaturesCol(featuresNames)
```

(continues on next page)
xgbClassifier.setLabelCol(labelName)
xgbClassifier.setMaxDepth(2)

### Note

In contrast with XGBoost4j-Spark which accepts both a feature column with VectorUDT type and an array of feature column names, XGBoost4j-Spark-GPU only accepts an array of feature column names by 

```java
setFeaturesCol(value: Array[String])
```

After setting XGBoostClassifier parameters and feature/label columns, we can build a transformer, XGBoostClassificationModel by fitting XGBoostClassifier with the input DataFrame. This fit operation is essentially the training process and the generated model can then be used in other tasks like prediction.

```java
val xgbClassificationModel = xgbClassifier.fit(train)
```

### Prediction

When we get a model, either a XGBoostClassificationModel or a XGBoostRegressionModel, it takes a DataFrame as an input, reads the column containing feature vectors, predicts for each feature vector, and outputs a new DataFrame with the following columns by default:

- XGBoostClassificationModel will output margins (rawPredictionCol), probabilities(probabilityCol) and the eventual prediction labels (predictionCol) for each possible label.
- XGBoostRegressionModel will output prediction a label(predictionCol).

```java
val xgbClassificationModel = xgbClassifier.fit(train)
val results = xgbClassificationModel.transform(test)
results.show()
```

With the above code snippet, we get a DataFrame as result, which contains the margin, probability for each class, and the prediction for each instance.

```

### Submit the application

Assuming you have configured the Spark standalone cluster with GPU support. Otherwise, please refer to spark standalone configuration with GPU support.

Starting from XGBoost 2.1.0, stage-level scheduling is automatically enabled. Therefore, if you are using Spark standalone cluster version 3.4.0 or higher, we strongly recommend configuring the "spark.task.resource.gpu.amount" as a fractional value. This will enable running multiple tasks in parallel during the ETL phase. An example configuration would be "spark.task.resource.gpu.amount=1/spark.executor.cores". However, if you are using a XGBoost version earlier than 2.1.0 or a Spark standalone cluster version below 3.4.0, you still need to set "spark.task.resource.gpu.amount" equal to "spark.executor.resource.gpu.amount".

#### Note

As of now, the stage-level scheduling feature in XGBoost is limited to the Spark standalone cluster mode. However, we have plans to expand its compatibility to YARN and Kubernetes once Spark 3.5.1 is officially released.

Assuming that the application main class is “Iris” and the application jar is “iris-1.0.0.jar”, provided below is an instance demonstrating how to submit the xgboost application to an Apache Spark Standalone cluster.
```bash
rapids_version=23.10.0
xgboost_version=2.0.1
main_class=Iris
app_jar=iris-1.0.0.jar

spark-submit \
   --master $master \
   --packages com.nvidia:rapids-4-spark_2.12:${rapids_version},ml.dmlc:xgboost4j-gpu_2.12:>${xgboost_version},ml.dmlc:xgboost4j-spark-gpu_2.12:${xgboost_version} \
   --conf spark.executor.cores=12 \n   --conf spark.task.cpus=1 \n   --conf spark.executor.resource.gpu.amount=1 \n   --conf spark.task.resource.gpu.amount=0.08 \n   --conf spark.rapids.sql.csv.read.double.enabled=true \n   --conf spark.rapids.sql.hasNans=false \n   --conf spark.rapids.sql.plugins=com.nvidia.spark.SQLPlugin \n   --class ${main_class} \n   ${app_jar}
```

- First, we need to specify the RAPIDS Accelerator, xgboost4j-gpu, xgboost4j-spark-gpu packages by `--packages`
- Second, RAPIDS Accelerator is a Spark plugin, so we need to configure it by specifying `spark.plugins=com.nvidia.spark.SQLPlugin`

For details about other RAPIDS Accelerator other configurations, please refer to the configuration.
For RAPIDS Accelerator Frequently Asked Questions, please refer to the frequently-asked-questions.

### API Docs for the JVM packages

- XGBoost4J Java API
- XGBoost4J Scala API
- XGBoost4J-Spark Scala API
- XGBoost4J-Flink Scala API

⚠️ **Note**

Please note that the flink interface is still under construction.

### 1.13 XGBoost.jl

See XGBoost.jl Project page.
1.14 XGBoost C Package

XGBoost implements a set of C API designed for various bindings, we maintain its stability and the CMake/make build interface. See C API Tutorial for an introduction and demo/c-api/ for related examples. Also one can generate doxygen document by providing -DBUILD_C_DOC=ON as parameter to CMake during build, or simply look at function comments in include/xgboost/c_api.h. The reference is exported to sphinx with the help of breathe, which doesn't contain links to examples but might be easier to read. For the original doxygen pages please visit:

- C API documentation (latest master branch)
- C API documentation (last stable release)

1.14.1 C API Reference

- **Library**
- **DMatrix**
  - **Streaming**
- **Booster**
  - **Prediction**
  - **Serialization**
- **Collective**

**Library**

*group Library*

These functions are used to obtain general information about XGBoost including version, build info and current global configuration.

**Typedefs**

typedef void *DMatrixHandle
    handle to DMatrix

typedef void *BoosterHandle
    handle to Booster
Functions

void XGBoostVersion(int *major, int *minor, int *patch)

Return the version of the XGBoost library being currently used.

The output variable is only written if it’s not NULL.

Parameters

• major – Store the major version number
• minor – Store the minor version number
• patch – Store the patch (revision) number

int XGBuildInfo(char const **out)

Get compile information of shared library.

Parameters

out – string encoded JSON object containing build flags and dependency version.

Returns

0 for success, -1 for failure

const char *XGBGetLastError()

get string message of the last error

all function in this file will return 0 when success and -1 when an error occurred, XGBGetLastError can be called to retrieve the error

this function is thread safe and can be called by different thread

Returns

const char* error information

int XGBRegisterLogCallback(void (*callback)(const char*))

register callback function for LOG(INFO) messages — helpful messages that are not errors. Note: this function can be called by multiple threads. The callback function will run on the thread that registered it

Returns

0 for success, -1 for failure

int XGBSetGlobalConfig(char const *config)

Set global configuration (collection of parameters that apply globally). This function accepts the list of key-value pairs representing the global-scope parameters to be configured. The list of key-value pairs are passed in as a JSON string.

Parameters

config – a JSON string representing the list of key-value pairs. The JSON object shall be flat: no value can be a JSON object or an array.

Returns

0 for success, -1 for failure

int XGBGetGlobalConfig(char const **out_config)

Get current global configuration (collection of parameters that apply globally).

Parameters

out_config – pointer to received returned global configuration, represented as a JSON string.
**Returns**

0 for success, -1 for failure

**DMatrix**

**group DMatrix**

DMatrix is the basic data storage for XGBoost used by all XGBoost algorithms including both training, prediction and explanation. There are a few variants of DMatrix including normal DMatrix, which is a CSR matrix, QuantileDMatrix, which is used by histogram-based tree methods for saving memory, and lastly the experimental external-memory-based DMatrix, which reads data in batches during training. For the last two variants, see the Streaming group.

**Functions**

```c
int XGDMatrixCreateFromFile(const char *fname, int silent, DMatrixHandle *out)
```

load a data matrix

* Deprecated: since 2.0.0*

```c
int XGDMatrixCreateFromURI(char const *config, DMatrixHandle *out)
```

load a data matrix

* uri: The URI of the input file. The URI parameter format is required when loading text data. See Text Input Format of DMatrix for more info.

* silent (optional): Whether to print message during loading. Default to true.

* data_split_mode (optional): Whether the file was split by row or column beforehand for distributed computing. Default to row.

**Parameters**

- `fname` – the name of the file
- `silent` – whether print messages during loading
- `out` – a loaded data matrix

**Returns**

0 when success, -1 when failure happens

* See also

XGDMatrixCreateFromURI()

- `config` – JSON encoded parameters for DMatrix construction. Accepted fields are:
Returns
0 when success, -1 when failure happens

int XGDMatrixCreateFromCSREx(const size_t *indptr, const unsigned *indices, const float *data, size_t nindptr, size_t nelem, size_t num_col, DMatrixHandle *out)

create a matrix content from CSR format

Deprecated:
since 2.0.0

See also
XGDMatrixCreateFromCSR()

int XGDMatrixCreateFromColumnar(char const *data, char const *config, DMatrixHandle *out)
Create a DMatrix from columnar data. (table)

Parameters
• data – See XGBoosterPredictFromColumnar for details.
• config – See XGDMatrixCreateFromDense for details.
• out – The created dmatrix.

Returns
0 when success, -1 when failure happens

int XGDMatrixCreateFromCSR(char const *indptr, char const *indices, char const *data, bst_ulong ncol, char const *config, DMatrixHandle *out)
Create a matrix from CSR matrix.

Parameters
• indptr – JSON encoded array_interface to row pointers in CSR.
• indices – JSON encoded array_interface to column indices in CSR.
• data – JSON encoded array_interface to values in CSR.
• ncol – Number of columns.
• config – JSON encoded configuration. Required values are:
  – missing: Which value to represent missing value.
  – nthread (optional): Number of threads used for initializing DMatrix.
  – data_split_mode (optional): Whether the data was split by row or column beforehand. Default to row.
• out – created dmatrix

Returns
0 when success, -1 when failure happens

int XGDMatrixCreateFromDense(char const *data, char const *config, DMatrixHandle *out)
Create a matrix from dense array.

Parameters
• **data** – JSON encoded *array_interface* to array values.

• **config** – JSON encoded configuration. Required values are:
  – missing: Which value to represent missing value.
  – nthread (optional): Number of threads used for initializing DMatrix.
  – data_split_mode (optional): Whether the data was split by row or column beforehand. Default to row.

• **out** – created dmatrix

**Returns**

0 when success, -1 when failure happens

```c
int XGDMatrixCreateFromCSC(char const *indptr, char const *indices, char const *data, bst_ulong nrow, char const *config, DMatrixHandle *out)
```

Create a matrix from a CSC matrix.

**Parameters**

• **indptr** – JSON encoded *array_interface* to column pointers in CSC.

• **indices** – JSON encoded *array_interface* to row indices in CSC.

• **data** – JSON encoded *array_interface* to values in CSC.

• **nrow** – number of rows in the matrix.

• **config** – JSON encoded configuration. Supported values are:
  – missing: Which value to represent missing value.
  – nthread (optional): Number of threads used for initializing DMatrix.
  – data_split_mode (optional): Whether the data was split by row or column beforehand. Default to row.

• **out** – created dmatrix

**Returns**

0 when success, -1 when failure happens

```c
int XGDMatrixCreateFromCSCEx(const size_t *col_ptr, const unsigned *indices, const float *data, size_t nindptr, size_t nelem, size_t num_row, DMatrixHandle *out)
```

create a matrix content from CSC format

**Deprecated:**

since 2.0.0

**See also**

`XGDMatrixCreateFromCSC()`

```c
int XGDMatrixCreateFromMat(const float *data, bst_ulong nrow, bst_ulong ncol, float missing, DMatrixHandle *out)
```

create matrix content from dense matrix

**Parameters**
• data – pointer to the data space
• nrow – number of rows
• ncol – number columns
• missing – which value to represent missing value
• out – created dmatrix

Returns
0 when success, -1 when failure happens

int XGDMatrixCreateFromMat_omp(const float *data, bst_ulong nrow, bst_ulong ncol, float missing,
                              DMatrixHandle *out, int nthread)

create matrix content from dense matrix

Parameters
• data – pointer to the data space
• nrow – number of rows
• ncol – number columns
• missing – which value to represent missing value
• out – created dmatrix
• nthread – number of threads (up to maximum cores available, if <=0 use all cores)

Returns
0 when success, -1 when failure happens

int XGDMatrixCreateFromDT(void **data, const char **feature_stypes, bst_ulong nrow, bst_ulong ncol,
                           DMatrixHandle *out, int nthread)

create matrix content from python data table

Parameters
• data – pointer to pointer to column data
• feature_stypes – pointer to strings
• nrow – number of rows
• ncol – number columns
• out – created dmatrix
• nthread – number of threads (up to maximum cores available, if <=0 use all cores)

Returns
0 when success, -1 when failure happens

int XGDMatrixCreateFromCudaColumnar(char const *data, char const *config, DMatrixHandle *out)
Create DMatrix from CUDA columnar format. (cuDF)

Parameters
• data – Array of JSON encoded cuda_array_interface for each column.
• config – JSON encoded configuration. Required values are:
  – missing: Which value to represent missing value.
  – nthread (optional): Number of threads used for initializing DMatrix.
– data_split_mode (optional): Whether the data was split by row or column beforehand. Default to row.

• out – created dmatrix

Returns
0 when success, -1 when failure happens

int XGDMatrixCreateFromCudaArrayInterface(char const *data, char const *config, DMatrixHandle *out)

Create DMatrix from CUDA array.

Parameters
• data – JSON encoded cuda_array_interface for array data.
• config – JSON encoded configuration. Required values are:
  – missing: Which value to represent missing value.
  – nthread (optional): Number of threads used for initializing DMatrix.
  – data_split_mode (optional): Whether the data was split by row or column beforehand. Default to row.
• out – created dmatrix

Returns
0 when success, -1 when failure happens

int XGDMatrixSliceDMatrix(DMatrixHandle handle, const int *idxset, bst_ulong len, DMatrixHandle *out)

create a new dmatrix from sliced content of existing matrix

Parameters
• handle – instance of data matrix to be sliced
• idxset – index set
• len – length of index set
• out – a sliced new matrix

Returns
0 when success, -1 when failure happens

int XGDMatrixSliceDMatrixEx(DMatrixHandle handle, const int *idxset, bst_ulong len, DMatrixHandle *out, int allow_groups)

create a new dmatrix from sliced content of existing matrix

Parameters
• handle – instance of data matrix to be sliced
• idxset – index set
• len – length of index set
• out – a sliced new matrix
• allow_groups – allow slicing of an array with groups

Returns
0 when success, -1 when failure happens
int **XGDMatrixFree(DMatrixHandle handle)**

free space in data matrix

**Returns**
- 0 when success, -1 when failure happens

int **XGDMatrixSaveBinary(DMatrixHandle handle, const char *fname, int silent)**

load a data matrix into binary file

**Parameters**
- **handle** – a instance of data matrix
- **fname** – file name
- **silent** – print statistics when saving

**Returns**
- 0 when success, -1 when failure happens

int **XGDMatrixSetInfoFromInterface(DMatrixHandle handle, char const *field, char const *c_interface_str)**

Set content in array interface to a content in info.

**Parameters**
- **handle** – a instance of data matrix
- **field** – field name.
- **c_interface_str** – JSON string representation of array interface.

**Returns**
- 0 when success, -1 when failure happens

int **XGDMatrixSetFloatInfo(DMatrixHandle handle, const char *field, const float *array, bst_ulong len)**

set float vector to a content in info

**Parameters**
- **handle** – a instance of data matrix
- **field** – field name, can be label, weight
- **array** – pointer to float vector
- **len** – length of array

**Returns**
- 0 when success, -1 when failure happens

int **XGDMatrixSetUIntInfo(DMatrixHandle handle, const char *field, const unsigned *array, bst_ulong len)**

**Deprecated:**
- since 2.1.0

Use **XGDMatrixSetInfoFromInterface** instead.

int **XGDMatrixSetStrFeatureInfo(DMatrixHandle handle, const char *field, const char **features, const bst_ulong size)**

Set string encoded information of all features.

Accepted fields are:
- **feature_name**
• feature_type

```c
char const* feat_names [] = {"feat_0", "feat_1"};
XGDMatrixSetStrFeatureInfo(handle, "feature_name", feat_names, 2);
```

// i for integer, q for quantitative, c for categorical. Similarly "int" and "float"
// are also recognized.
```c
char const* feat_types [] = {"i", "q"};
XGDMatrixSetStrFeatureInfo(handle, "feature_type", feat_types, 2);
```

Parameters

- **handle** — An instance of data matrix
- **field** — Field name
- **features** — Pointer to array of strings.
- **size** — Size of features pointer (number of strings passed in).

Returns

0 when success, -1 when failure happens

```c
int XGDMatrixGetStrFeatureInfo(DMatrixHandle handle, const char *field, bst_ulong *size, const char ***out_features)
```

Get string encoded information of all features.

Accepted fields are:

- feature_name
- feature_type

Caller is responsible for copying out the data, before next call to any API function of XGBoost.

```c
char const **c_out_features = NULL;
bst_ulong out_size = 0;
```

// Assuming the feature names are already set by `XGDMatrixSetStrFeatureInfo`.
```c
XGDMatrixGetStrFeatureInfo(handle, "feature_name", &out_size,
                           &c_out_features)
```

```c
for (bst_ulong i = 0; i < out_size; ++i) {
    // Here we are simply printing the string. Copy it out if the feature name is
    // useful after printing.
    printf("feature %lu: %s\n", i, c_out_features[i]);
}
```

Parameters

- **handle** — An instance of data matrix
- **field** — Field name
- **size** — Size of output pointer features (number of strings returned).
• **out_features** – Address of a pointer to array of strings. Result is stored in thread local memory.

**Returns**
0 when success, -1 when failure happens

```c
int XGDMatrixSetDenseInfo(DMatrixHandle handle, const char *field, void const *data, bst_ulong size, int type)
```

*Deprecated:* since 2.1.0
Use `XGDMatrixSetInfoFromInterface` instead.

```c
int XGDMatrixGetFloatInfo(const DMatrixHandle handle, const char *field, bst_ulong *out_len, const float **out_dptr)
```

get float info vector from matrix.

**Parameters**
- **handle** – a instance of data matrix
- **field** – field name
- **out_len** – used to set result length
- **out_dptr** – pointer to the result

**Returns**
0 when success, -1 when failure happens

```c
int XGDMatrixGetUIntInfo(const DMatrixHandle handle, const char *field, bst_ulong *out_len, const unsigned **out_dptr)
```

get uint32 info vector from matrix

**Parameters**
- **handle** – a instance of data matrix
- **field** – field name
- **out_len** – The length of the field.
- **out_dptr** – pointer to the result

**Returns**
0 when success, -1 when failure happens

```c
int XGDMatrixNumRow(DMatrixHandle handle, bst_ulong *out)
```

get number of rows.

**Parameters**
- **handle** – the handle to the DMatrix
- **out** – The address to hold number of rows.

**Returns**
0 when success, -1 when failure happens

```c
int XGDMatrixNumCol(DMatrixHandle handle, bst_ulong *out)
```

get number of columns.

**Parameters**
xgboost, Release 2.1.1

- **handle** – the handle to the DMatrix
- **out** – The output of number of columns

**Returns**
0 when success, -1 when failure happens

```c
int XGDMatrixNumNonMissing(DMatrixHandle handle, bst_ulong *out)
```
Get number of valid values from DMatrix.

**Parameters**
- **handle** – the handle to the DMatrix
- **out** – The output of number of non-missing values

**Returns**
0 when success, -1 when failure happens

```c
int XGDMatrixDataSplitMode(DMatrixHandle handle, bst_ulong *out)
```
Get the data split mode from DMatrix.

**Parameters**
- **handle** – the handle to the DMatrix
- **out** – The output of the data split mode

**Returns**
0 when success, -1 when failure happens

```c
int XGDMatrixGetDataAsCSR(DMatrixHandle const handle, char const *config, bst_ulong *out_indptr,
                          unsigned *out_indices, float *out_data)
```
Get the predictors from DMatrix as CSR matrix for testing. If this is a quantized DMatrix, quantized values are returned instead.

Unlike most of XGBoost C functions, caller of `XGDMatrixGetDataAsCSR` is required to allocate the memory for return buffer instead of using thread local memory from XGBoost. This is to avoid allocating a huge memory buffer that can not be freed until exiting the thread.

Since 1.7.0

**Parameters**
- **handle** – the handle to the DMatrix
- **config** – JSON configuration string. At the moment it should be an empty document, preserved for future use.
- **out_indptr** – indptr of output CSR matrix.
- **out_indices** – Column index of output CSR matrix.
- **out_data** – Data value of CSR matrix.

**Returns**
0 when success, -1 when failure happens
int XGDMatrixGetQuantileCut(DMatrixHandle const handle, char const *config, char const **out_indptr, char const **out_data)

Export the quantile cuts used for training histogram-based models like hist and approx. Useful for model compression.

Since 2.0.0

Parameters

- **handle** – the handle to the DMatrix
- **config** – JSON configuration string. At the moment it should be an empty document, preserved for future use.
- **out_indptr** – indptr of output CSC matrix represented by a JSON encoded __(cuda_)array_interface__.
- **out_data** – Data value of CSC matrix represented by a JSON encoded __(cuda_)array_interface__.

Streaming

**group Streaming**

Quantile DMatrix and external memory DMatrix can be created from batches of data.

There are 2 sets of data callbacks for DMatrix. The first one is currently exclusively used by JVM packages. It uses XGBoostBatchCSR to accept batches for CSR formatted input, and concatenate them into 1 final big CSR. The related functions are:

- **XGBCallbackSetData**
- **XGBCallbackDataIterNext**
- **XGDMatrixCreateFromDataIter**

Another set is used by external data iterator. It accept foreign data iterators as callbacks. There are 2 different senarios where users might want to pass in callbacks instead of raw data. First it’s the Quantile DMatrix used by hist and GPU Hist. For this case, the data is first compressed by quantile sketching then merged. This is particular useful for distributed setting as it eliminates 2 copies of data. 1 by a concat from external library to make the data into a blob for normal DMatrix initialization, another by the internal CSR copy of DMatrix. The second use case is external memory support where users can pass a custom data iterator into XGBoost for loading data in batches. There are short notes on each of the use cases in respected DMatrix factory function.

Related functions are:
Factory functions

- `XGMatrixCreateFromCallback` for external memory
- `XGQuantileDMatrixCreateFromCallback` for quantile DMatrix

Proxy that callers can use to pass data to XGBoost

- `XGProxyDMatrixCreate`
- `XGProxyDMatrixCallbackNext`
- `DataIterResetCallback`
- `XGProxyDMatrixSetDataCudaArrayInterface`
- `XGProxyDMatrixSetDataCudaColumnar`
- `XGProxyDMatrixSetDataDense`
- `XGProxyDMatrixSetDataCSR`
- … (data setters)

Typedefs

typedef void *DataIterHandle
    handle to a external data iterator

typedef void *DataHolderHandle
    handle to a internal data holder.

typedef int XGCallbackSetData(DataHolderHandle handle, XGBoostBatchCSR batch)
    Callback to set the data to handle.

    **Param handle**
    The handle to the callback.

    **Param batch**
    The data content to be set.

typedef int XGCallbackDataIterNext(DataIterHandle data_handle, XGCallbackSetData *set_function,
    DataHolderHandle set_function_handle)
    The data reading callback function. The iterator will be able to give subset of batch in the data.

    If there is data, the function will call set_function to set the data.

    **Param data_handle**
    The handle to the callback.

    **Param set_function**
    The batch returned by the iterator

    **Param set_function_handle**
    The handle to be passed to set function.
Return
0 if we are reaching the end and batch is not returned.

typedef int XGDMatrixCallbackNext(DataIterHandle iter)
Callback function prototype for getting next batch of data.

Param iter
A handler to the user defined iterator.

Return
0 when success, -1 when failure happens

typedef void DataIterResetCallback(DataIterHandle handle)
Callback function prototype for resetting external iterator.

Functions

int XGDMatrixCreateFromDataIter(DataIterHandle data_handle, XGBCallbackDataIterNext *callback,
const char *cache_info, float missing,
DMatrixHandle *out)
Create a DMatrix from a data iterator.

Parameters
• data_handle – The handle to the data.
• callback – The callback to get the data.
• cache_info – Additional information about cache file, can be null.
• missing – Which value to represent missing value.
• out – The created DMatrix

Returns
0 when success, -1 when failure happens.

int XGProxyDMatrixCreate(DMatrixHandle *out)
Create a DMatrix proxy for setting data, can be free by XGDMatrixFree.

Second set of callback functions, used by constructing Quantile DMatrix or external memory DMatrix
using custom iterator.

Parameters
out – The created Device Quantile DMatrix

Returns
0 when success, -1 when failure happens

int XGDMatrixCreateFromCallback(DataIterHandle iter, DMatrixHandle proxy, DataIterResetCallback
*reset, XGDMatrixCallbackNext *next, char const *config,
DMatrixHandle *out)
Create an external memory DMatrix with data iterator.

Short note for how to use second set of callback for external memory data support:

• Step 0: Define a data iterator with 2 methods reset, and next.
• Step 1: Create a DMatrix proxy by XGProxyDMatrixCreate and hold the handle.
• Step 2: Pass the iterator handle, proxy handle and 2 methods into `XGDMatrixCreateFromCallback`, along with other parameters encoded as a JSON object.

• Step 3: Call appropriate data setters in `next` functions.

Parameters

• `iter` – A handle to external data iterator.

• `proxy` – A DMatrix proxy handle created by `XGProxyDMatrixCreate`.

• `reset` – Callback function resetting the iterator state.

• `next` – Callback function yielding the next batch of data.

• `config` – JSON encoded parameters for DMatrix construction. Accepted fields are:
  – `missing`: Which value to represent missing value
  – `cache_prefix`: The path of cache file, caller must initialize all the directories in this path.
  – `nthread` (optional): Number of threads used for initializing DMatrix.

• `out` – [out] The created external memory DMatrix

Returns

0 when success, -1 when failure happens

```c
int XGQuantileDMatrixCreateFromCallback(DataIterHandle iter, DMatrixHandle proxy, DataIterHandle ref, DataIterResetCallback *reset, XGDMatrixCallbackNext *next, char const *config, DMatrixHandle *out)
```

Create a Quantile DMatrix with data iterator.

Short note for how to use the second set of callback for (GPU)Hist tree method:

• Step 0: Define a data iterator with 2 methods `reset`, and `next`.

• Step 1: Create a DMatrix proxy by `XGProxyDMatrixCreate` and hold the handle.

• Step 2: Pass the iterator handle, proxy handle and 2 methods into `XGQuantileDMatrixCreateFromCallback`.

• Step 3: Call appropriate data setters in `next` functions.

See test_iterative_dmatrix.cu or Python interface for examples.

Parameters

• `iter` – A handle to external data iterator.

• `proxy` – A DMatrix proxy handle created by `XGProxyDMatrixCreate`.

• `ref` – Reference DMatrix for providing quantile information.

• `reset` – Callback function resetting the iterator state.

• `next` – Callback function yielding the next batch of data.

• `config` – JSON encoded parameters for DMatrix construction. Accepted fields are:
  – `missing`: Which value to represent missing value
  – `nthread` (optional): Number of threads used for initializing DMatrix.
  – `max_bin` (optional): Maximum number of bins for building histogram.
• **out** – The created Quantile DMatrix.

**Returns**
0 when success, -1 when failure happens

```c
int XGDeviceQuantileDMatrixCreateFromCallback(DataIterHandle iter, DMatrixHandle proxy,
                                           DataIterResetCallback *reset,
                                           XGDMatrixCallbackNext *next, float missing, int nthread, int max_bin, DMatrixHandle *out)
```

Create a Device Quantile DMatrix with data iterator.

*Deprecated:* since 1.7.0

---

**See also**

`XGQuantileDMatrixCreateFromCallback()`

```c
int XGProxyDMatrixSetDataCudaArrayInterface(DMatrixHandle handle, const char *c_interface_str)
```

Set data on a DMatrix proxy.

**Parameters**

- **handle** – A DMatrix proxy created by `XGProxyDMatrixCreate`
- **c_interface_str** – Null terminated JSON document string representation of CUDA array interface.

**Returns**
0 when success, -1 when failure happens

```c
int XGProxyDMatrixSetDataColumnar(DMatrixHandle handle, char const *c_interface_str)
```

Set columnar (table) data on a DMatrix proxy.

**Parameters**

- **handle** – A DMatrix proxy created by `XGProxyDMatrixCreate`
- **c_interface_str** – See `XGBoosterPredictFromColumnar` for details.

**Returns**
0 when success, -1 when failure happens

```c
int XGProxyDMatrixSetDataCudaColumnar(DMatrixHandle handle, const char *c_interface_str)
```

Set data on a DMatrix proxy.

**Parameters**

- **handle** – A DMatrix proxy created by `XGProxyDMatrixCreate`
- **c_interface_str** – Null terminated JSON document string representation of CUDA array interface, with an array of columns.

**Returns**
0 when success, -1 when failure happens

```c
int XGProxyDMatrixSetDataDense(DMatrixHandle handle, char const *c_interface_str)
```

Set data on a DMatrix proxy.

**Parameters**
• **handle** – A DMatrix proxy created by `XGProxyDMatrixCreate`

• **c_interface_str** – Null terminated JSON document string representation of array interface.

**Returns**
0 when success, -1 when failure happens

```c
int XGProxyDMatrixSetDataCSR(DMatrixHandle handle, char const *indptr, char const *indices, char const *data, bst_ulong ncol)
```

Set data on a DMatrix proxy.

**Parameters**
• **handle** – A DMatrix proxy created by `XGProxyDMatrixCreate`

• **indptr** – JSON encoded array interface to row pointer in CSR.

• **indices** – JSON encoded array interface to column indices in CSR.

• **data** – JSON encoded array interface to values in CSR.

• **ncol** – The number of columns of input CSR matrix.

**Returns**
0 when success, -1 when failure happens

```c
struct XGBoostBatchCSR
```

#include `<c_api.h>` Mini batch used in XGBoost Data Iteration.

## Booster

### `group Booster`

The `Booster` class is the gradient-boosted model for XGBoost.

### Functions

```c
int XGBoosterCreate(const DMatrixHandle dmats[], bst_ulong len, BoosterHandle *out)
```

create xgboost learner

**Parameters**
• **dmats** – matrices that are set to be cached

• **len** – length of dmats

• **out** – handle to the result booster

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterFree(BoosterHandle handle)
```

free obj in handle

**Parameters**
• **handle** – handle to be freed

**Returns**
0 when success, -1 when failure happens
int XGBoosterSlice(BoosterHandle handle, int begin_layer, int end_layer, int step, BoosterHandle *out)
Slice a model using boosting index. The slice m:n indicates taking all trees that were fit during the boosting rounds m, (m+1), (m+2), ..., (n-1).

Parameters
- handle – Booster to be sliced.
- begin_layer – start of the slice
- end_layer – end of the slice; end_layer=0 is equivalent to end_layer=num_boost_round
- step – step size of the slice
- out – Sliced booster.

Returns
0 when success, -1 when failure happens, -2 when index is out of bound.

int XGBoosterBoostedRounds(BoosterHandle handle, int *out)
Get number of boosted rounds from gradient booster. When process_type is update, this number might drop due to removed tree.

Parameters
- handle – Handle to booster.
- out – Pointer to output integer.

Returns
0 when success, -1 when failure happens

int XGBoosterSetParam(BoosterHandle handle, const char *name, const char *value)
set parameters

Parameters
- handle – handle
- name – parameter name
- value – value of parameter

Returns
0 when success, -1 when failure happens

int XGBoosterGetNumFeature(BoosterHandle handle, bst_ulong *out)
get number of features

Parameters
- handle – Handle to booster.
- out – number of features

Returns
0 when success, -1 when failure happens

int XGBoosterUpdateOneIter(BoosterHandle handle, int iter, DMatrixHandle dtrain)
update the model in one round using dtrain

Parameters
- handle – handle
- iter – current iteration rounds
• **dtrain** – training data

Returns

0 when success, -1 when failure happens

```c
int XGBoosterBoostOneIter(BoosterHandle handle, DMatrixHandle dtrain, float *grad, float *hess,
                          bst_ulong len)
```

*Deprecated:*

since 2.1.0

```c
int XGBoosterTrainOneIter(BoosterHandle handle, DMatrixHandle dtrain, int iter, char const *grad, char const *hess)
```

Update a model with gradient and Hessian. This is used for training with a custom objective function.

Since

2.0.0

Parameters

• **handle** – handle

• **dtrain** – The training data.

• **iter** – The current iteration round. When training continuation is used, the count should restart.

• **grad** – Json encoded __(cuda)_array_interface__ for gradient.

• **hess** – Json encoded __(cuda)_array_interface__ for Hessian.

Returns

0 when success, -1 when failure happens

```c
int XGBoosterEvalOneIter(BoosterHandle handle, int iter, DMatrixHandle dmats[], const char *evnames[],
                          bst_ulong len, const char **out_result)
```

get evaluation statistics for xgboost

Parameters

• **handle** – handle

• **iter** – current iteration rounds

• **dmats** – pointers to data to be evaluated

• **evnames** – pointers to names of each data

• **len** – length of dmats

• **out_result** – the string containing evaluation statistics

Returns

0 when success, -1 when failure happens

```c
int XGBoosterDumpModel(BoosterHandle handle, const char *fmap, int with_stats, bst_ulong *out_len, const char ***out_dump_array)
```

dump model, return array of strings representing model dump

Parameters

• **handle** – handle
- **fmap** – name to fmap can be empty string
- **with_stats** – whether to dump with statistics
- **out_len** – length of output array
- **out_dump_array** – pointer to hold representing dump of each model

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterDumpModelEx(BoosterHandle handle, const char *fmap, int with_stats, const char *format,
                         bst_ulong *out_len, const char ***out_dump_array)
```
dump model, return array of strings representing model dump

**Parameters**
- **handle** – handle
- **fmap** – name to fmap can be empty string
- **with_stats** – whether to dump with statistics
- **format** – the format to dump the model in
- **out_len** – length of output array
- **out_dump_array** – pointer to hold representing dump of each model

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterDumpModelWithFeatures(BoosterHandle handle, int fnum, const char **fname, const char **ftype,
                                    int with_stats, bst_ulong *out_len, const char ***out_models)
```
dump model, return array of strings representing model dump

**Parameters**
- **handle** – handle
- **fnum** – number of features
- **fname** – names of features
- **ftype** – types of features
- **with_stats** – whether to dump with statistics
- **out_len** – length of output array
- **out_models** – pointer to hold representing dump of each model

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterDumpModelExWithFeatures(BoosterHandle handle, int fnum, const char **fname, const char **ftype,
                                     int with_stats, const char *format, bst_ulong *out_len,
                                     const char ***out_models)
```
dump model, return array of strings representing model dump

**Parameters**
- **handle** – handle
- **fnum** – number of features
- **fname** – names of features
- **ftype** – types of features
- **with_stats** – whether to dump with statistics
- **format** – the format to dump the model in
- **out_len** – length of output array
- **out_models** – pointer to hold representing dump of each model

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterGetAttr(BoosterHandle handle, const char *key, const char **out, int *success)
```

Get string attribute from Booster.

**Parameters**
- **handle** – handle
- **key** – The key of the attribute.
- **out** – The result attribute, can be NULL if the attribute do not exist.
- **success** – Whether the result is contained in out.

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterSetAttr(BoosterHandle handle, const char *key, const char *value)
```

Set or delete string attribute.

**Parameters**
- **handle** – handle
- **key** – The key of the attribute.
- **value** – The value to be saved. If nullptr, the attribute would be deleted.

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterGetAttrNames(BoosterHandle handle, bst_ulong *out_len, const char ***out)
```

Get the names of all attribute from Booster.

**Parameters**
- **handle** – handle
- **out_len** – the argument to hold the output length
- **out** – pointer to hold the output attribute stings

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterSetStrFeatureInfo(BoosterHandle handle, const char *field, const char **features, const bst_ulong size)
```

Set string encoded feature info in Booster, similar to the feature info in DMatrix.

Accepted fields are:
- **feature_name**
• feature_type

Parameters
• handle – An instance of Booster
• field – Field name
• features – Pointer to array of strings.
• size – Size of features pointer (number of strings passed in).

Returns
0 when success, -1 when failure happens

int XGBoosterGetStrFeatureInfo(BoosterHandle handle, const char *field, bst_ulong *len, const char ***out_features)

Get string encoded feature info from Booster, similar to feature info in DMatrix.
Accepted fields are:
• feature_name
• feature_type
Caller is responsible for copying out the data, before next call to any API function of XGBoost.

Parameters
• handle – An instance of Booster
• field – Field name
• len – Size of output pointer features (number of strings returned).
• out_features – Address of a pointer to array of strings. Result is stored in thread local memory.

Returns
0 when success, -1 when failure happens

int XGBoosterFeatureScore(BoosterHandle handle, const char *config, bst_ulong *out_n_features, char const ***out_features, bst_ulong *out_dim, bst_ulong const **out_shape, float const **out_scores)

Calculate feature scores for tree models. When used on linear model, only the weight importance type is defined, and output scores is a row major matrix with shape [n_features, n_classes] for multi-class model. For tree model, out_n_feature is always equal to out_n_scores and has multiple definitions of importance type.

Parameters
• handle – An instance of Booster
• config – Parameters for computing scores encoded as JSON. Accepted JSON keys are:
  – importance_type: A JSON string with following possible values:
    * ‘weight’: the number of times a feature is used to split the data across all trees.
    * ‘gain’: the average gain across all splits the feature is used in.
    * ‘cover’: the average coverage across all splits the feature is used in.
    * ‘total_gain’: the total gain across all splits the feature is used in.
    * ‘total_cover’: the total coverage across all splits the feature is used in.
– feature_map: An optional JSON string with URI or path to the feature map file.
– feature_names: An optional JSON array with string names for each feature.
- out_n_features – Length of output feature names.
- out_features – An array of string as feature names, ordered the same as output scores.
- out_dim – Dimension of output feature scores.
- out_shape – Shape of output feature scores with length of out_dim.
- out_scores – An array of floating point as feature scores with shape of out_shape.

Returns
0 when success, -1 when failure happens

Prediction

group Prediction
These functions are used for running prediction and explanation algorithms.

Functions

int XGBoosterPredict(BoosterHandle handle, DMatrixHandle dmat, int option_mask, unsigned ntree_limit, int training, bst_ulong *out_len, const float **out_result)

make prediction based on dmat (deprecated, use XGBoosterPredictFromDMatrix instead)

Deprecated:

See also
XGBoosterPredictFromDMatrix()

Parameters

- handle – handle
- dmat – data matrix
- option_mask – bit-mask of options taken in prediction, possible values 0:normal prediction 1:output margin instead of transformed value 2:output leaf index of trees instead of leaf value, note leaf index is unique per tree 4:output feature contributions to individual predictions
- ntree_limit – limit number of trees used for prediction, this is only valid for boosted trees when the parameter is set to 0, we will use all the trees
- training – Whether the prediction function is used as part of a training loop. Prediction can be run in 2 scenarios:
  a. Given data matrix X, obtain prediction y_pred from the model.
b. Obtain the prediction for computing gradients. For example, DART booster performs dropout during training, and the prediction result will be different from the one obtained by normal inference step due to dropped trees. Set training=false for the first scenario. Set training=true for the second scenario. The second scenario applies when you are defining a custom objective function.

- **out_len** – used to store length of returning result
- **out_result** – used to set a pointer to array

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterPredictFromDMatrix(BoosterHandle handle, DMatrixHandle dmat, char const *config,
                                bst_ulong const **out_shape, bst_ulong *out_dim, float const *
                                **out_result)
```

Make prediction from DMatrix, replacing `XGBoosterPredict`.

“type”: [0, 6]
- 0: normal prediction
- 1: output margin
- 2: predict contribution
- 3: predict approximated contribution
- 4: predict feature interaction
- 5: predict approximated feature interaction
- 6: predict leaf “training”: bool Whether the prediction function is used as part of a training loop.
  **Not used for inplace prediction.**

Prediction can be run in 2 scenarios:

a. Given data matrix X, obtain prediction y_pred from the model.

b. Obtain the prediction for computing gradients. For example, DART booster performs dropout during training, and the prediction result will be different from the one obtained by normal inference step due to dropped trees. Set training=false for the first scenario. Set training=true for the second scenario. The second scenario applies when you are defining a custom objective function. “iteration_begin”: int Beginning iteration of prediction. “iteration_end”: int End iteration of prediction. Set to 0 this will become the size of tree model (all the trees). “strict_shape”: bool Whether should we reshape the output with stricter rules. If set to true, normal/margin/contrib/interaction predict will output consistent shape disregarding the use of multi-class model, and leaf prediction will output 4-dim array representing: (n_samples, n_iterations, n_classes, n_trees_in_forest)

Example JSON input for running a normal prediction with strict output shape, 2 dim for softprob, 1 dim for others.

```json
{
   "type": 0,
   "training": false,
   "iteration_begin": 0,
   "iteration_end": 0,
   "strict_shape": true
}
```
Parameters
- **handle** – Booster handle
- **dmat** – DMatrix handle
- **config** – String encoded predict configuration in JSON format, with following available fields in the JSON object:
  - **out_shape** – Shape of output prediction (copy before use).
  - **out_dim** – Dimension of output prediction.
  - **out_result** – Buffer storing prediction value (copy before use).

Returns
0 when success, -1 when failure happens

```c
int XGBoosterPredictFromDense(BosterHandle handle, char const *values, char const *config,
                              DMatrixHandle m, bst_ulong const **out_shape, bst_ulong *out_dim,
                              const float **out_result)
```

Inplace prediction from CPU dense matrix.

**Note**
If the booster is configured to run on a CUDA device, XGBoost falls back to run prediction with DMatrix with a performance warning.

Parameters
- **handle** – Booster handle.
- **values** – JSON encoded `array_interface` to values.
- **config** – See `XGBoosterPredictFromDMatrix` for more info. Additional fields for inplace prediction are:
  - "missing": float
- **m** – An optional (NULL if not available) proxy DMatrix instance storing meta info.
- **out_shape** – See `XGBoosterPredictFromDMatrix` for more info.
- **out_dim** – See `XGBoosterPredictFromDMatrix` for more info.
- **out_result** – See `XGBoosterPredictFromDMatrix` for more info.

Returns
0 when success, -1 when failure happens
**XGBoosterPredictFromColumnar**

```c
int XGBoosterPredictFromColumnar(BoosterHandle handle, char const *values, char const *config,
                                  DMatrixHandle m, bst_ulong const **out_shape, bst_ulong
                                  *out_dim, const float **out_result)
```

Inplace prediction from CPU columnar data. (Table)

### Note

If the booster is configured to run on a CUDA device, XGBoost falls back to run prediction with DMatrix with a performance warning.

#### Parameters

- **handle** – Booster handle.
- **values** – An JSON array of `array_interface` for each column.
- **config** – See `XGBoosterPredictFromDMatrix` for more info. Additional fields for inplace prediction are:
  - "missing": float
- **m** – An optional (NULL if not available) proxy DMatrix instance storing meta info.
- **out_shape** – See `XGBoosterPredictFromDMatrix` for more info.
- **out_dim** – See `XGBoosterPredictFromDMatrix` for more info.
- **out_result** – See `XGBoosterPredictFromDMatrix` for more info.

#### Returns

0 when success, -1 when failure happens

**XGBoosterPredictFromCSR**

```c
int XGBoosterPredictFromCSR(BoosterHandle handle, char const *indptr, char const *indices, char const
                             *values, bst_ulong ncol, char const *config, DMatrixHandle m, bst_ulong
                             const **out_shape, bst_ulong *out_dim, const float **out_result)
```

Inplace prediction from CPU CSR matrix.

### Note

If the booster is configured to run on a CUDA device, XGBoost falls back to run prediction with DMatrix with a performance warning.

#### Parameters

- **handle** – Booster handle.
- **indptr** – JSON encoded `array_interface` to row pointer in CSR.
- **indices** – JSON encoded `array_interface` to column indices in CSR.
- **values** – JSON encoded `array_interface` to values in CSR.
- **ncol** – Number of features in data.
- **config** – See `XGBoosterPredictFromDMatrix` for more info. Additional fields for inplace prediction are:
  - "missing": float
- **m** – An optional (NULL if not available) proxy DMatrix instance storing meta info.
• **out_shape** – See `XGBoosterPredictFromDMatrix` for more info.
• **out_dim** – See `XGBoosterPredictFromDMatrix` for more info.
• **out_result** – See `XGBoosterPredictFromDMatrix` for more info.

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterPredictFromCudaArray(BoosterHandle handle, char const *values, char const *config, DMatrixHandle m, bst_ulong const **out_shape, bst_ulong *out_dim, const float **out_result)
```

Inplace prediction from CUDA Dense matrix (cupy in Python).

**Note**
If the booster is configured to run on a CPU, XGBoost falls back to run prediction with DMatrix with a performance warning.

**Parameters**
- **handle** – Booster handle
- **values** – JSON encoded `cuda_array_interface` to values.
- **config** – See `XGBoosterPredictFromDMatrix` for more info. Additional fields for inplace prediction are:
  - "missing": float
- **m** – An optional (NULL if not available) proxy DMatrix instance storing meta info.
- **out_shape** – See `XGBoosterPredictFromDMatrix` for more info.
- **out_dim** – See `XGBoosterPredictFromDMatrix` for more info.
- **out_result** – See `XGBoosterPredictFromDMatrix` for more info.

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterPredictFromCudaColumnar(BoosterHandle handle, char const *values, char const *config, DMatrixHandle m, bst_ulong const **out_shape, bst_ulong *out_dim, const float **out_result)
```

Inplace prediction from CUDA dense dataframe (cuDF in Python).

**Note**
If the booster is configured to run on a CPU, XGBoost falls back to run prediction with DMatrix with a performance warning.

**Parameters**
- **handle** – Booster handle
- **values** – List of `cuda_array_interface` for all columns encoded in JSON list.
- **config** – See `XGBoosterPredictFromDMatrix` for more info. Additional fields for inplace prediction are:
- "missing": float
  - m – An optional (NULL if not available) proxy DMatrix instance storing meta info.
  - out_shape – See XGBoosterPredictFromDMatrix for more info.
  - out_dim – See XGBoosterPredictFromDMatrix for more info.
  - out_result – See XGBoosterPredictFromDMatrix for more info.

Returns
0 when success, -1 when failure happens

Serialization

group Serialization
There are multiple ways to serialize a Booster object depending on the use case.

Short note for serialization APIs. There are 3 different sets of serialization API.

- Functions with the term “Model” handles saving/loading XGBoost model like trees or linear weights. Stripping out parameters configuration like training algorithms or CUDA device ID. These functions are designed to let users reuse the trained model for different tasks, examples are prediction, training continuation or model interpretation.

- Functions with the term “Config” handles save/loading configuration. It helps user to study the internal of XGBoost. Also user can use the load method for specifying parameters in a structured way. These functions are introduced in 1.0.0, and are not yet stable.

- Functions with the term “Serialization” are combined of above two. They are used in situations like checkpointing, or continuing training task in distributed environment. In these cases the task must be carried out without any user intervention.

Functions

int XGBoosterLoadModel(BoosterHandle handle, const char *fname)
Load model from existing file.

Parameters
  - handle – handle
  - fname – File URI or file name. The string must be UTF-8 encoded.

Returns
0 when success, -1 when failure happens

int XGBoosterSaveModel(BoosterHandle handle, const char *fname)
Save model into existing file.

Parameters
  - handle – handle
  - fname – File URI or file name. The string must be UTF-8 encoded.

Returns
0 when success, -1 when failure happens
int XGBoosterLoadModelFromBuffer(BoosterHandle handle, const void *buf, bst_ulong len)
load model from in memory buffer

Parameters

• handle – handle
• buf – pointer to the buffer
• len – the length of the buffer

Returns
0 when success, -1 when failure happens

int XGBoosterSaveModelToBuffer(BoosterHandle handle, char const *config, bst_ulong *out_len, char const **out_dptr)
Save model into raw bytes, return header of the array. User must copy the result out, before next xgboost call.

Parameters

• handle – handle
• config – JSON encoded string storing parameters for the function. Following keys are expected in the JSON document:
  – "format": str
    * json: Output booster will be encoded as JSON.
    * ubj: Output booster will be encoded as Universal binary JSON.
    * deprecated: Output booster will be encoded as old custom binary format. Do not use this format except for compatibility reasons.
• out_len – The argument to hold the output length
• out_dptr – The argument to hold the output data pointer

Returns
0 when success, -1 when failure happens

int XGBoosterSerializeToBuffer(BoosterHandle handle, bst_ulong *out_len, const char **out_dptr)
Memory snapshot based serialization method. Saves everything states into buffer.

Parameters

• handle – handle
• out_len – the argument to hold the output length
• out_dptr – the argument to hold the output data pointer

Returns
0 when success, -1 when failure happens

int XGBoosterUnserializeFromBuffer(BoosterHandle handle, const void *buf, bst_ulong len)
Memory snapshot based serialization method. Loads the buffer returned from XGBoosterSerializeToBuffer.

Parameters

• handle – handle
• buf – pointer to the buffer
xgboost, Release 2.1.1

- **len** – the length of the buffer

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterSaveJsonConfig(BoosterHandle handle, bst_ulong *out_len, char const **out_str)
```

Save XGBoost’s internal configuration into a JSON document. Currently the support is experimental, function signature may change in the future without notice.

**Parameters**
- **handle** – handle to Booster object.
- **out_len** – length of output string
- **out_str** – A valid pointer to array of characters. The characters array is allocated and
  managed by XGBoost, while pointer to that array needs to be managed by caller.

**Returns**
0 when success, -1 when failure happens

```c
int XGBoosterLoadJsonConfig(BoosterHandle handle, char const *config)
```

Load XGBoost’s internal configuration from a JSON document. Currently the support is experimental, function signature may change in the future without notice.

**Parameters**
- **handle** – handle to Booster object.
- **config** – string representation of a JSON document.

**Returns**
0 when success, -1 when failure happens

**Collective**

**group Collective**
Experimental support for exposing internal communicator in XGBoost.

The collective communicator in XGBoost evolved from the rabbit project of dmlc but has changed significantly since its adoption. It consists of a tracker and a set of workers. The tracker is responsible for bootstrapping the communication group and handling centralized tasks like logging. The workers are actual communicators performing collective tasks like allreduce.

To use the collective implementation, one needs to first create a tracker with corresponding parameters, then get the arguments for workers using `XGTrackerWorkerArgs()`. The obtained arguments can then be passed to the `XGCommunicatorInit()` function. Call to `XGCommunicatorInit()` must be accompanied with a `XGCommunicatorFinalize()` call for cleanups. Please note that the communicator uses std::thread in C++, which has undefined behavior in a C++ destructor due to the runtime shutdown sequence. It’s preferable to call `XGCommunicatorFinalize()` before the runtime is shutting down. This requirement is similar to a Python thread or socket, which should not be relied upon in a __del__ function.

Since it’s used as a part of XGBoost, errors will be returned when a XGBoost function is called, for instance, training a booster might return a connection error.
Note

This is still under development.

**Typedefs**

typedef void *TrackerHandle

Handle to the tracker.

There are currently two types of tracker in XGBoost, first one is `rabit`, while the other one is `federated`. `rabit` is used for normal collective communication, while `federated` is used for federated learning.

**Functions**

```c
int XGTrackerCreate(char const *config, TrackerHandle *handle)
```

Create a new tracker.

- `dmlc_communicator`: String, the type of tracker to create. Available options are `rabit` and `federated`. See `TrackerHandle` for more info.
- `n_workers`: Integer, the number of workers.
- `port`: (Optional) Integer, the port this tracker should listen to.
- `timeout`: (Optional) Integer, timeout in seconds for various networking operations. Default is 300 seconds.

Some configurations are `rabit` specific:

- `host`: (Optional) String, Used by the `rabit` tracker to specify the address of the host. This can be useful when the communicator cannot reliably obtain the host address.
- `sortby`: (Optional) Integer.
  - `0`: Sort workers by their host name.
  - `1`: Sort workers by task IDs.

Some `federated` specific configurations:

- `federated_secure`: Boolean, whether this is a secure server. False for testing.
- `server_key_path`: Path to the server key. Used only if this is a secure server.
- `server_cert_path`: Path to the server certificate. Used only if this is a secure server.
- `client_cert_path`: Path to the client certificate. Used only if this is a secure server.

**Parameters**

- `config` – JSON encoded parameters.
- `handle` – The handle to the created tracker.

**Returns**

0 for success, -1 for failure.
int **XGTrackerWorkerArgs(TrackerHandle handle, char const **args)

Get the arguments needed for running workers. This should be called after XGTrackerRun().

Parameters

• handle – The handle to the tracker.

• args – The arguments returned as a JSON document.

Returns

0 for success, -1 for failure.

int XGTrackerRun(TrackerHandle handle, char const *config)

Start the tracker. The tracker runs in the background and this function returns once the tracker is started.

Parameters

• handle – The handle to the tracker.

• config – Unused at the moment, preserved for the future.

Returns

0 for success, -1 for failure.

int XGTrackerWaitFor(TrackerHandle handle, char const *config)

Wait for the tracker to finish, should be called after XGTrackerRun(). This function will block until the tracker task is finished or timeout is reached.

Parameters

• handle – The handle to the tracker.

• config – JSON encoded configuration. No argument is required yet, preserved for the future.

Returns

0 for success, -1 for failure.

int XGTrackerFree(TrackerHandle handle)

Free a tracker instance. This should be called after XGTrackerWaitFor(). If the tracker is not properly waited, this function will shutdown all connections with the tracker, potentially leading to undefined behavior.

Parameters

handle – The handle to the tracker.

Returns

0 for success, -1 for failure.

int XGCommunicatorInit(char const *config)

Initialize the collective communicator.

Currently the communicator API is experimental, function signatures may change in the future without notice.

Call this once in the worker process before using anything. Please make sure XGCommunicatorFinalize() is called after use. The initialized communicator is a global thread-local variable.

Only applicable to the rabbit communicator:

• dmlc_tracker_uri: Hostname or IP address of the tracker.

• dmlc_tracker_port: Port number of the tracker.
• dmlc_task_id: ID of the current task, can be used to obtain deterministic rank assignment.
• dmlc_retry: The number of retries for connection failure.
• dmlc_timeout: Timeout in seconds.
• dmlc_nccl_path: Path to the nccl shared library libnccl.so.

Only applicable to the federated communicator (use upper case for environment variables, use lower case for runtime configuration):

• federated_server_address: Address of the federated server.
• federated_world_size: Number of federated workers.
• federated_rank: Rank of the current worker.
• federated_server_cert_path: Server certificate file path. Only needed for the SSL mode.
• federated_client_key_path: Client key file path. Only needed for the SSL mode.
• federated_client_cert_path: Client certificate file path. Only needed for the SSL mode.

Parameters
config – JSON encoded configuration. Accepted JSON keys are:
• dmlc_communicator: The type of the communicator, this should match the tracker type.
  – rabit: Use Rabit. This is the default if the type is unspecified.
  – federated: Use the gRPC interface for Federated Learning.

Returns
0 for success, -1 for failure.

int XGCommunicatorFinalize(void)
Finalize the collective communicator.
Call this function after you have finished all jobs.

Returns
0 for success, -1 for failure.

int XGCommunicatorGetRank(void)
Get rank of the current process.

Returns
Rank of the worker.

int XGCommunicatorGetWorldSize(void)
Get the total number of processes.

Returns
Total world size.

int XGCommunicatorIsDistributed(void)
Get if the communicator is distributed.

Returns
True if the communicator is distributed.
int XGCommunicatorPrint(char const *message)
    Print the message to the tracker.
    This function can be used to communicate the information of the progress to the user who monitors the tracker.

    Parameters
    message – The message to be printed.

    Returns
    0 for success, -1 for failure.

int XGCommunicatorGetProcessorName(const char **name_str)
    Get the name of the processor.

    Parameters
    name_str – Pointer to received returned processor name.

    Returns
    0 for success, -1 for failure.

int XGCommunicatorBroadcast(void *send_receive_buffer, size_t size, int root)
    Broadcast a memory region to all others from root. This function is NOT thread-safe.

Example:

```c
int a = 1;
Broadcast(&a, sizeof(a), root);
```

Parameters
- **send_receive_buffer** – Pointer to the send or receive buffer.
- **size** – Size of the data in bytes.
- **root** – The process rank to broadcast from.

Returns
0 for success, -1 for failure.

int XGCommunicatorAllreduce(void *send_receive_buffer, size_t count, int data_type, int op)
    Perform in-place allreduce. This function is NOT thread-safe.

Example Usage: the following code gives sum of the result

```c
enum class Op {
    kMax = 0, kMin = 1, kSum = 2, kBitwiseAND = 3, kBitwiseOR = 4, kBitwiseXOR,
    ... = 5
};
std::vector<int> data(10);
...
Allreduce(data.data(), data.size(), DataType::kInt32, Op::kSum);
...
```

Parameters
- **send_receive_buffer** – Buffer for both sending and receiving data.
- **count** – Number of elements to be reduced.
• **data_type** – Enumeration of data type, see xgboost::collective::DataType in communicator.h.

• **op** – Enumeration of operation type, see xgboost::collective::Operation in communicator.h.

**Returns**

0 for success, -1 for failure.

### 1.15 XGBoost C++ API

Starting from 1.0 release, CMake will generate installation rules to export all C++ headers. But the C++ interface is much closer to the internal of XGBoost than other language bindings. As a result it’s changing quite often and we don’t maintain its stability. Along with the plugin system (see plugin/example in XGBoost’s source tree), users can utilize some existing C++ headers for gaining more access to the internal of XGBoost.

- C++ interface documentation (latest master branch)
- C++ interface documentation (last stable release)

### 1.16 XGBoost Command Line version

See XGBoost Command Line walkthrough.

### 1.17 Contribute to XGBoost

XGBoost has been developed by community members. Everyone is welcome to contribute. We value all forms of contributions, including, but not limited to:

- Code reviews for pull requests
- Documentation and usage examples
- Community participation in forums and issues
- Code readability and developer guide
  - We welcome contributions that add code comments to improve readability.
  - We also welcome contributions to docs to explain the design choices of the XGBoost internals.
- Test cases to make the codebase more robust.
- Tutorials, blog posts, talks that promote the project.

Here are guidelines for contributing to various aspect of the XGBoost project:
1.17.1 XGBoost Community Guideline

XGBoost adopts the Apache style model and governs by merit. We believe that it is important to create an inclusive community where everyone can use, contribute to, and influence the direction of the project. See `CONTRIBUTORS.md` for the current list of contributors.

General Development Process

Everyone in the community is welcomed to send patches, documents, and propose new directions to the project. The key guideline here is to enable everyone in the community to get involved and participate in the decision and development. When major changes are proposed, an RFC should be sent to allow discussion by the community. We encourage public discussion, archivable channels such as issues and discuss forum, so that everyone in the community can participate and review the process later.

Code reviews are one of the key ways to ensure the quality of the code. High-quality code reviews prevent technical debt for long-term and are crucial to the success of the project. A pull request needs to be reviewed before it gets merged. A committer who has the expertise of the corresponding area would moderate the pull request and then merge the code when it is ready. The corresponding committer could request multiple reviewers who are familiar with the area of the code. We encourage contributors to request code reviews themselves and help review each other’s code – remember everyone is volunteering their time to the community, high-quality code review itself costs as much as the actual code contribution, you could get your code quickly reviewed if you do others the same favor.

The community should strive to reach a consensus on technical decisions through discussion. We expect committers and PMCs to moderate technical discussions in a diplomatic way, and provide suggestions with clear technical reasoning when necessary.

Committers

Committers are individuals who are granted the write access to the project. A committer is usually responsible for a certain area or several areas of the code where they oversee the code review process. The area of contribution can take all forms, including code contributions and code reviews, documents, education, and outreach. Committers are essential for a high quality and healthy project. The community actively look for new committers from contributors. Here is a list of useful traits that help the community to recognize potential committers:

- Sustained contribution to the project, demonstrated by discussion over RFCs, code reviews and proposals of new features, and other development activities. Being familiar with, and being able to take ownership on one or several areas of the project.

- Quality of contributions: High-quality, readable code contributions indicated by pull requests that can be merged without a substantial code review. History of creating clean, maintainable code and including good test cases. Informative code reviews to help other contributors that adhere to a good standard.

- Community involvement: active participation in the discussion forum, promote the projects via tutorials, talks and outreach. We encourage committers to collaborate broadly, e.g. do code reviews and discuss designs with community members that they do not interact physically.

The Project Management Committee (PMC) consists of a group of active committers that moderate the discussion, manage the project release, and proposes new committer/PMC members. Potential candidates are usually proposed via an internal discussion among PMCs, followed by a consensus approval, i.e. least 3 +1 votes, and no vetoes. Any veto must be accompanied by reasoning. PMCs should serve the community by upholding the community practices and guidelines in order to make XGBoost a better community for everyone. PMCs should strive to only nominate new candidates outside of their own organization.

The PMC is in charge of the project’s continuous integration (CI) and testing infrastructure. Currently, we host our own Jenkins server at https://xgboost-ci.net. The PMC shall appoint committer(s) to manage the CI infrastructure.
The PMC may accept 3rd-party donations and sponsorships that would defray the cost of the CI infrastructure. See \textit{Donations}.

\textbf{Reviewers}

Reviewers are individuals who actively contributed to the project and are willing to participate in the code review of new contributions. We identify reviewers from active contributors. The committers should explicitly solicit reviews from reviewers. High-quality code reviews prevent technical debt for the long-term and are crucial to the success of the project. A pull request to the project has to be reviewed by at least one reviewer in order to be merged.

\textbf{1.17.2 Donations}

\textbf{Motivation}

DMLC/XGBoost has grown from a research project incubated in academia to one of the most widely used gradient boosting framework in production environment. On one side, with the growth of volume and variety of data in the production environment, users are putting accordingly growing expectation to XGBoost in terms of more functions, scalability and robustness. On the other side, as an open source project which develops in a fast pace, XGBoost has been receiving contributions from many individuals and organizations around the world. Given the high expectation from the users and the increasing channels of contribution to the project, delivering the high quality software presents a challenge to the project maintainers.

A robust and efficient \textit{continuous integration (CI)} infrastructure is one of the most critical solutions to address the above challenge. A CI service will monitor an open-source repository and run a suite of integration tests for every incoming contribution. This way, the CI ensures that every proposed change in the codebase is compatible with existing functionalities. Furthermore, XGBoost can enable more thorough tests with a powerful CI infrastructure to cover cases which are closer to the production environment.

There are several CI services available free to open source projects, such as Travis CI and AppVeyor. The XGBoost project already utilizes GitHub Actions. However, the XGBoost project has needs that these free services do not adequately address. In particular, the limited usage quota of resources such as CPU and memory leaves XGBoost developers unable to bring “too-intensive” tests. In addition, they do not offer test machines with GPUs for testing XGBoost-GPU code base which has been attracting more and more interest across many organizations. Consequently, the XGBoost project uses a cloud-hosted test farm. We use BuildKite to organize CI pipelines.

The cloud-hosted test farm has recurring operating expenses. It utilizes a leading cloud provider (AWS) to accommodate variable workload. BuildKite launches worker machines on AWS on demand, to run the test suite on incoming contributions. To save cost, the worker machines are terminated when they are no longer needed.

To help defray the hosting cost, the XGBoost project seeks donations from third parties.

\textbf{Donations and Sponsorships}

Donors may choose to make one-time donations or recurring donations on monthly or yearly basis. Donors who commit to the Sponsor tier will have their logo displayed on the front page of the XGBoost project.
**Fiscal host: Open Source Collective 501(c)(6)**

The Project Management Committee (PMC) of the XGBoost project appointed Open Source Collective as their fiscal host. The platform is a 501(c)(6) registered entity and will manage the funds on the behalf of the PMC so that PMC members will not have to manage the funds directly. The platform currently hosts several well-known JavaScript frameworks such as Babel, Vue, and Webpack.

All expenses incurred for hosting CI will be submitted to the fiscal host with receipts. Only the expenses in the following categories will be approved for reimbursement:

- Cloud expenses for the cloud test farm (https://buildkite.com/xgboost)
- Cost of domain https://xgboost-ci.net
- Monthly cost of using BuildKite
- Hosting cost of the User Forum (https://discuss.xgboost.ai)

**Administration of cloud CI infrastructure**

The PMC shall appoint committer(s) to administer the cloud CI infrastructure on their behalf. The current administrators are as follows:

- Primary administrator: Hyunsu Cho
- Secondary administrator: Jiaming Yuan

The administrators shall make good-faith effort to keep the CI expenses under control. The expenses shall not exceed the available funds. The administrators should post regular updates on CI expenses.

**1.17.3 Coding Guideline**

Contents

- C++ Coding Guideline
- Python Coding Guideline
- R Coding Guideline
  - Code Style
  - Rmarkdown Vignettes
  - R package versioning
  - Testing R package with different compilers
  - Registering native routines in R
  - Generating the Package and Running Tests
- Running Formatting Checks Locally
  - Linter
  - Clang-tidy
- Guide for handling user input data
C++ Coding Guideline

• Follow Google style for C++, with two exceptions:
  – Each line of text may contain up to 100 characters.
  – The use of C++ exceptions is allowed.
• Use C++17 features such as smart pointers, braced initializers, lambda functions, and std::thread.
• Use Doxygen to document all the interface code.
• We have some comments around symbols imported by headers, some of those are hinted by include-what-you-use. It’s not required.
• We use clang-tidy and clang-format. You can check their configuration in the root directory of the XGBoost source tree.
• We have a series of automatic checks to ensure that all of our codebase complies with the Google style. Before submitting your pull request, you are encouraged to run the style checks on your machine. See R Coding Guideline.

Python Coding Guideline

• Follow PEP 8: Style Guide for Python Code. We use Pylint to automatically enforce PEP 8 style across our Python codebase. Before submitting your pull request, you are encouraged to run Pylint on your machine. See R Coding Guideline.
• Docstrings should be in NumPy docstring format.

R Coding Guideline

Code Style

• We follow Google’s C++ Style guide for C++ code.
  – This is mainly to be consistent with the rest of the project.
  – Another reason is we will be able to check style automatically with a linter.
• When needed, you can disable the linter warning of certain line with // NOLINT(*) comments.
• We use roxygen for documenting the R package.

Rmarkdown Vignettes

Rmarkdown vignettes are placed in R-package/vignettes. These Rmarkdown files are not compiled. We host the compiled version on doc/R-package.

The following steps are followed to add a new Rmarkdown vignettes:

• Add the original rmarkdown to R-package/vignettes.
• Modify doc/R-package/Makefile to add the markdown files to be build.
• Clone the dmlc/web-data repo to folder doc.
• Now type the following command on doc/R-package:
This will generate the markdown, as well as the figures in doc/web-data/xgboost/knitr.

- Modify the doc/R-package/index.md to point to the generated markdown.
- Add the generated figure to the dmlc/web-data repo.
  - If you already cloned the repo to doc, this means git add
- Create PR for both the markdown and dmlc/web-data.
- You can also build the document locally by typing the following command at the doc directory:

```
make html
```

The reason we do this is to avoid exploded repo size due to generated images.

## R package versioning

See [XGBoost Release Policy](#).

## Testing R package with different compilers

You can change the default compiler of R by changing the configuration file in home directory. For instance, if you want to test XGBoost built with clang++ instead of g++ on Linux, put the following in your `~/.R/Makevars` file:

```
CC=clang-15
CXX17=clang++-15
```

Be aware that the variable name should match with the name used by `R CMD`:

```
R CMD config CXX17
```

## Registering native routines in R

According to [R extension manual](#), it is good practice to register native routines and to disable symbol search. When any changes or additions are made to the C++ interface of the R package, please make corresponding changes in `src/init.c` as well.

## Generating the Package and Running Tests

The source layout of XGBoost is a bit unusual to normal R packages as XGBoost is primarily written in C++ with multiple language bindings in mind. As a result, some special cares need to be taken to generate a standard R tarball. Most of the tests are being run on CI, and as a result, the best way to see how things work is by looking at the CI configuration files (GitHub action, at the time of writing). There are helper scripts in `tests/ci_build` and `R-package/tests/helper_scripts` for running various checks including linter and making the standard tarball.
Running Formatting Checks Locally

Once you submit a pull request to dmlc/xgboost, we perform two automatic checks to enforce coding style conventions. To expedite the code review process, you are encouraged to run the checks locally on your machine prior to submitting your pull request.

**Linters**

We use a combination of linters to enforce style conventions and find potential errors. Linting is especially useful for scripting languages like Python, as we can catch many errors that would have otherwise occurred at run-time.

For Python scripts, **pylint**, **black** and **isort** are used for providing guidance on coding style, and **mypy** is required for type checking. For C++, **cpplint** is used along with **clang-tidy**. For R, **lintr** is used.

To run checks for Python locally, install the checkers mentioned previously and run:

```
cd /path/to/xgboost/
python ./tests/ci_build/lint_python.py --fix
```

To run checks for R:

```
cd /path/to/xgboost/
R CMD INSTALL R-package/
Rscript tests/ci_build/lint_r.R $(pwd)
```

To run checks for cpplint locally:

```
cd /path/to/xgboost/
python ./tests/ci_build/lint_cpp.py
```

See next section for clang-tidy. For CMake scripts:

```
bash ./tests/ci_build/lint_cmake.sh
```

Lastly, the linter for jvm-packages is integrated into the maven build process.

**Clang-tidy**

**Clang-tidy** is an advanced linter for C++ code, made by the LLVM team. We use it to conform our C++ codebase to modern C++ practices and conventions.

To run this check locally, run the following command from the top level source tree:

```
cd /path/to/xgboost/
python3 tests/ci_build/tidy.py
```

Also, the script accepts two optional integer arguments, namely **--cpp** and **--cuda**. By default they are both set to 1, meaning that both C++ and CUDA code will be checked. If the CUDA toolkit is not installed on your machine, you’ll encounter an error. To exclude CUDA source from linting, use:

```
cd /path/to/xgboost/
python3 tests/ci_build/tidy.py --cuda=0
```

Similarly, if you want to exclude C++ source from linting:
Guide for handling user input data

This is an in-comprehensive guide for handling user input data. XGBoost has wide verity of native supported data structures, mostly come from higher level language bindings. The inputs ranges from basic contiguous 1 dimension memory buffer to more sophisticated data structures like columnar data with validity mask. Raw input data can be used in 2 places, firstly it’s the construction of various DMatrix, secondly it’s the in-place prediction. For plain memory buffer, there’s not much to discuss since it’s just a pointer with a size. But for general n-dimension array and columnar data, there are many subtleties. XGBoost has 3 different data structures for handling optionally masked arrays (tensors), for consuming user inputs ArrayInterface should be chosen. There are many existing functions that accept only plain pointer due to legacy reasons (XGBoost started as a much simpler library and didn’t care about memory usage that much back then). The ArrayInterface is a in memory representation of __array_interface__ protocol defined by numpy or the __cuda_array_interface__ defined by numba. Following is a checklist of things to have in mind when accepting related user inputs:

- [] Is it strided? (identified by the strides field)
- [] If it’s a vector, is it row vector or column vector? (Identified by both shape and strides).
- [] Is the data type supported? Half type and 128 integer types should be converted before going into XGBoost.
- [] Does it have higher than 1 dimension? (identified by shape field)
- [] Are some of dimensions trivial? (shape[dim] <= 1)
- [] Does it have mask? (identified by mask field)
- [] Can the mask be broadcasted? (unsupported at the moment)
- [] Is it on CUDA memory? (identified by data field, and optionally stream)

Most of the checks are handled by the ArrayInterface during construction, except for the data type issue since it doesn’t know how to cast such pointers with C builtin types. But for safety reason one should still try to write related tests for the all items. The data type issue should be taken care of in language binding for each of the specific data input. For single-chunk columnar format, it’s just a masked array for each column so it should be treated uniformly as normal array. For input predictor X, we have adapters for each type of input. Some are composition of the others. For instance, CSR matrix has 3 potentially strided arrays for indptr, indices and values. No assumption should be made to these components (all the check boxes should be considered). Slicing row of CSR matrix should calculate the offset of each field based on respective strides.

For meta info like labels, which is growing both in size and complexity, we accept only masked array at the moment (no specialized adapter). One should be careful about the input data shape. For base margin it can be 2 dim or higher if we have multiple targets in the future. The getters in DMatrix returns only 1 dimension flatten vectors at the moment, which can be improved in the future when it’s needed.
1.17.4 Consistency for Language Bindings

XGBoost has many different language bindings developed over the years, some are in the main repository while others live independently. Many features and interfaces are inconsistent with each others, this document aims to provide some guidelines and actionable items for language binding designers.

Model Serialization

XGBoost C API exposes a couple functions for serializing a model for persistence storage. These saved files are backward compatible, meaning one can load an older XGBoost model with a newer XGBoost version. If there’s change in the model format, we have deprecation notice inside the C++ implementation and public issue for tracking the status. See Introduction to Model IO for details.

As a result, these are considered to be stable and should work across language bindings. For instance, a model trained in R should be fully functioning in C or Python. Please don’t pad anything to the output file or buffer.

If there are extra fields that must be saved:

- First review whether the attribute can be retrieved from known properties of the model. For instance, there’s a classes_ attribute in the scikit-learn interface XGBClassifier, which can be obtained through numpy.arange(n_classes) and doesn’t need to be saved into the model. Preserving version compatibility is not a trivial task and we are still spending a significant amount of time to maintain it. Please don’t make complication if it’s not necessary.

- Then please consider whether it’s universal. For instance, we have added feature_types to the model serialization for categorical features (which is a new feature after 1.6), the attribute is useful or will be useful in the future regardless of the language binding.

- If the field is small, we can save it as model attribute (which is a key-value structure). These attributes are ignored by all other language bindings and mostly an ad-hoc storage.

- Lastly, we should use the UBJSON as the default output format when given a chance (not to be burdened by the old binary format).

Training Continuation

There are cases where we want to train a model based on the previous model, for boosting trees, it’s either adding new trees or modifying the existing trees. This can be normal model update, error recovery, or other special cases we don’t know of yet. When it happens, the training iteration should start from 0, not from the last boosted rounds of the model. 0 is a special iteration number, we perform some extra checks like whether the label is valid during that iteration. These checks can be expensive but necessary for eliminating silent errors. Keeping the iteration starts from zero allows us to perform these checks only once for each input data.

Inference

The inference function is quite inconsistent among language bindings at the time of writing due to historical reasons, but this makes more important for us to have consistency in mind in the future development.

- Firstly, it’s the output shape. There’s a relatively new parameter called strict_shape in XGBoost and is rarely used. We want to make it as the default behavior but couldn’t due to compatibility concerns. See Prediction for details. In short, if specified, XGBoost C++ implementation can output prediction with the correct shape, instead of letting the language binding to handle it.

- Policy around early stopping is at the moment inconsistent between various interfaces. Some considers the best_iteration attribute while others don’t. We should formalize that all interfaces in the future should use the best_iteration during inference unless user has explicitly specified the iteration_range parameter.
Parameter naming

There are many parameter naming conventions out there. Some XGBoost interfaces try to align with the larger communities. For example, the R package might support parameters naming like max_depth=3, while the Spark package might support MaxDepth=3. These are fine, it’s better for the users to keep their pipeline consistent. However, while supporting naming variants, the normal, XGBoost way of naming should also be supported, meaning max_depth=3 should be a valid parameter no-matter what language one is using. If someone were to write duplicated parameter max_depth=3, max_depth=3, a clear error should be preferred instead of prioritizing one over the other.

Default Parameters

Like many other machine learning libraries, all parameters from XGBoost can either be inferred from the data or have default values. Bindings should not make copies of these default values and let the XGBoost core decide. When the parameter key is not passed into the C++ core, XGBoost will pick the default accordingly. These defaults are not necessarily optimal, but they are there for consistency. If there’s a new choice of default parameter, we can change it inside the core and it will be automatically propagated to all bindings. Given the same set of parameters and data, various bindings should strive to produce the same model. One exception is the num_boost_rounds, which exists only in high-level bindings and has various alias like n_estimators. Its default value is close to arbitrary at the moment, we haven’t been able to get a good default yet.

Logging

XGBoost has a default logger builtin that can be a wrapper over binding-specific logging facility. For instance, the Python binding registers a callback to use Python warnings and print() function to output logging. We want to keep logging native to the larger communities instead of using the stderr from C++.

Minimum Amount of Data Manipulation

XGBoost is mostly a machine learning library providing boosting algorithm implementation. Some other implementations might perform some sort of data manipulation implicitly like deciding the coding of the data, and transforming the data according to some heuristic before training. We prefer to keep these operations based on necessities instead of convenience to keep the scope of the project well-defined. Whenever possible, we should leave these features to 3-party libraries and consider how a user can compose their pipeline. For instance, XGBoost itself should not perform ordinal encoding for categorical data, users will pick an encoder that fits their use cases (like out-of-core implementation, distributed implementation, known mapping, etc). If some transformations are decided to be part of the algorithm, we can have it inside the core instead of the language binding. Examples would be target-encoding or sketching the response variables. If we were to support them, we could have it inside the core implementation as part of the ML algorithm. This aligns with the same principles of default parameters, various bindings should provide similar (if not the same) results given the same set of parameters and data.

Feature Info

XGBoost accepts data structures that contain meta info about predictors, including the names and types of features. Example inputs are pandas.DataFrame, R data.frame. We have the following heuristics: - When the input data structure contains such information, we set the feature_names and feature_types for DMatrix accordingly. - When a user provides this information as explicit parameters, the user-provided version should override the one provided by the data structure. - When both sources are missing, the DMatrix class contain empty info.
1.17.5 Notes on packaging XGBoost’s Python package

How to build binary wheels and source distributions

Wheels and source distributions (sdist for short) are the two main mechanisms for packaging and distributing Python packages.

- A source distribution (sdist) is a tarball (.tar.gz extension) that contains the source code.
- A wheel is a ZIP-compressed archive (with .whl extension) representing a built distribution. Unlike an sdist, a wheel can contain compiled components. The compiled components are compiled prior to distribution, making it more convenient for end-users to install a wheel. Wheels containing compiled components are referred to as binary wheels.

See Python Packaging User Guide to learn more about how Python packages in general are packaged and distributed. For the remainder of this document, we will focus on packaging and distributing XGBoost.

Building sdists

In the case of XGBoost, an sdist contains both the Python code as well as the C++ code, so that the core part of XGBoost can be compiled into the shared library libxgboost.so.

You can obtain an sdist as follows:

```
$ python -m build --sdist .
```

(You’ll need to install the build package first: pip install build or conda install python-build.)

Running pip install with an sdist will launch CMake and a C++ compiler to compile the bundled C++ code into libxgboost.so:

```
$ pip install -v xgboost-2.0.0.tar.gz  # Add -v to show build progress
```

1 The name of the shared library file will differ depending on the operating system in use. See Building the Shared Library.
Building binary wheels

You can also build a wheel as follows:

$ pip wheel --no-deps -v .

Notably, the resulting wheel contains a copy of the shared library libxgboost.so. The wheel is a binary wheel, since it contains a compiled binary.

Running `pip install` with the binary wheel will extract the content of the wheel into the current Python environment. Since the wheel already contains a pre-built copy of libxgboost.so, it does not have to be built at the time of install. So `pip install` with the binary wheel completes quickly:

$ pip install xgboost-2.0.0-py3-none-linux_x86_64.whl  # Completes quickly

1.17.6 Adding and running tests

A high-quality suite of tests is crucial in ensuring correctness and robustness of the codebase. Here, we provide instructions how to run unit tests, and also how to add a new one.

Contents

- Adding a new unit test
  - Python package: pytest
  - C++: Google Test
  - JVM packages: JUnit / scalatest
  - R package: testthat

- Running Unit Tests Locally
  - R package
  - JVM packages
  - Python package: pytest
  - C++: Google Test

- Sanitizers: Detect memory errors and data races
  - How to build XGBoost with sanitizers
  - How to use sanitizers with CUDA support
  - Other sanitizer runtime options
Adding a new unit test

Python package: pytest

Add your test under the directories

- tests/python/
- tests/python-gpu/ (if you are testing GPU code)
- tests/test_distributed. (if a distributed framework is used)

Refer to the PyTest tutorial to learn how to write tests for Python code.
You may try running your test by following instructions in this section.

C++: Google Test

Add your test under the directory tests/cpp/. Refer to this excellent tutorial on using Google Test.
You may try running your test by following instructions in this section. Note. Google Test version 1.8.1 or later is required.

JVM packages: JUnit / scalatest

The JVM packages for XGBoost (XGBoost4J / XGBoost4J-Spark) use the Maven Standard Directory Layout. Specifically, the tests for the JVM packages are located in the following locations:

- jvm-packages/xgboost4j/src/test/
- jvm-packages/xgboost4j-spark/src/test/

To write a test for Java code, see JUnit 5 tutorial. To write a test for Scala, see Scalatest tutorial.
You may try running your test by following instructions in this section.

R package: testthat

Add your test under the directory R-package/tests/testthat. Refer to this excellent tutorial on testthat.
You may try running your test by following instructions in this section.

Running Unit Tests Locally

R package

Run

```
python ./tests/ci_build/test_r_package.py --task=check
```

at the root of the project directory. The command builds and checks the XGBoost r-package. Alternatively, if you want to just run the tests, you can use the following commands after installing XGBoost:

```
cd R-package/tests/
Rscript testthat.R
```
**JVM packages**

Maven is used

```
mvn test
```

**Python package: pytest**

To run Python unit tests, first install pytest package:

```
pip3 install pytest
```

Then compile XGBoost according to instructions in *Building the Shared Library*. Finally, invoke pytest at the project root directory:

```
# Tell Python where to find XGBoost module
export PYTHONPATH=./python-package
pytest -v -s --fulltrace tests/python
```

In addition, to test CUDA code, run:

```
# Tell Python where to find XGBoost module
export PYTHONPATH=./python-package
pytest -v -s --fulltrace tests/python-gpu
```

(For this step, you should have compiled XGBoost with CUDA enabled.)

For testing with distributed frameworks like Dask and PySpark:

```
# Tell Python where to find XGBoost module
export PYTHONPATH=./python-package
pytest -v -s --fulltrace tests/test_distributed
```

**C++: Google Test**

To build and run C++ unit tests enable tests while running CMake:

```
mkdir build
cd build
cmake -GNinja -DGOOGLE_TEST=ON -DUSE_DMLC_GTEST=ON -DUSE_CUDA=ON -DUSE_NCCL=ON ..
ninja
./testxgboost
```

Flags like `USE_CUDA`, `USE_DMLC_GTEST` are optional. For more info about how to build XGBoost from source, see *Building From Source*. One can also run all unit tests using ctest tool which provides higher flexibility. For example:

```
ctest --verbose
```

If you need to debug errors on Windows using the debugger from VS, you can append the gtest flags in `test_main.cc`:

```
::testing::GTEST_FLAG(filter) = "Suite.Test";
::testing::GTEST_FLAG(repeat) = 10;
```
Sanitizers: Detect memory errors and data races

By default, sanitizers are bundled in GCC and Clang/LLVM. One can enable sanitizers with GCC >= 4.8 or LLVM >= 3.1. But some distributions might package sanitizers separately. Here is a list of supported sanitizers with corresponding library names:

- Address sanitizer: libasan
- Undefined sanitizer: libubsan
- Leak sanitizer: liblsan
- Thread sanitizer: libtsan

Memory sanitizer is exclusive to LLVM, hence not supported in XGBoost. With latest compilers like gcc-9, when sanitizer flags are specified, the compiler driver should be able to link the runtime libraries automatically.

How to build XGBoost with sanitizers

One can build XGBoost with sanitizer support by specifying -DUSE_SANITIZER=ON. By default, address sanitizer and leak sanitizer are used when you turn the USE_SANITIZER flag on. You can always change the default by providing a semicolon separated list of sanitizers to ENABLED_SANITIZERS. Note that thread sanitizer is not compatible with the other two sanitizers.

```
cmake -DUSE_SANITIZER=ON -DENABLED_SANITIZERS="address;undefined" /path/to/xgboost
```

By default, CMake will search regular system paths for sanitizers, you can also supply a specified SANITIZER_PATH.

```
cmake -DUSE_SANITIZER=ON -DENABLED_SANITIZERS="address;undefined" -DSANITIZER_PATH=/path/to/sanitizers /path/to/xgboost
```

How to use sanitizers with CUDA support

Running XGBoost on CUDA with address sanitizer (asan) will raise memory error. To use asan with CUDA correctly, you need to configure asan via ASAN_OPTIONS environment variable:

```
ASAN_OPTIONS=protect_shadow_gap=0 ${BUILD_DIR}/testxgboost
```

Other sanitizer runtime options

By default undefined sanitizer doesn’t print out the backtrace. You can enable it by exporting environment variable:

```
UBSAN_OPTIONS=print_stacktrace=1 ${BUILD_DIR}/testxgboost
```

For details, please consult official documentation for sanitizers.
1.17.7 Documentation and Examples

Contents

• Documentation
  – Build the Python Docs using pip and Conda
• Examples

Documentation

• Python and C documentation is built using Sphinx.
• Each document is written in reStructuredText.
• The documentation is in the doc/ directory.
• You can build it locally using make html command.

make html

Run make help to learn about the other commands.

The online document is hosted by Read the Docs where the imported project is managed by Hyunsu Cho and Jiaming Yuan.

Build the Python Docs using pip and Conda

1. Create a conda environment.

conda create -n xgboost-docs --yes python=3.10

2. Activate the environment

conda activate xgboost-docs

3. Install required packages (in the current environment) using pip command.

pip install -r requirements.txt

1 Note

Python 3.10 is required by xgboost_ray package.

1 Note

It is currently not possible to install the required packages using conda due to xgboost_ray being unavailable in conda channels.

conda install --file requirements.txt --yes -c conda-forge
4. (optional) Install graphviz

```bash
conda install graphviz --yes
```

5. Eventually, build the docs.

```bash
make html
```

You should see the following messages in the console:

```
$ make html
sphinx-build -b html -d _build/doctrees . _build/html
Running Sphinx v6.2.1
...
The HTML pages are in _build/html.
Build finished. The HTML pages are in _build/html.
```

### Examples

- Use cases and examples are in demo directory.
- We are super excited to hear about your story. If you have blog posts, tutorials, or code solutions using XGBoost, please tell us, and we will add a link in the example pages.

### 1.17.8 XGBoost Internal Feature Map

The following is a reference to the features supported by XGBoost. It is not a beginner’s guide, but rather a list meant to help those looking to add new features to XGBoost understand what needs to be covered.

#### Core Features

Core features are not dependent on language binding and any language binding can choose to support them.

#### Data Storage

The primary data structure in XGBoost for storing user inputs is DMatrix; it’s a container for all data that XGBoost can use. QuantileDMatrix is a variant specifically designed for the hist tree method. Both can take GPU-based inputs. They take an optional parameter `missing` to specify which input value should be ignored. For external memory support, please refer to Using XGBoost External Memory Version.

#### Single Node Training

There are two different model types in XGBoost: the tree model, which we primarily focus on, and the linear model. For the tree model, we have various methods to build decision trees; please see the Tree Methods for a complete reference. In addition to the tree method, we have many hyper-parameters for tuning the model and injecting prior knowledge into the training process. Two noteworthy examples are monotonic constraints and feature interaction constraints. These two constraints require special treatment during tree construction. Both the hist and the approx tree methods support GPU acceleration. Also, XGBoost GPU supports gradient-based sampling, which supports external-memory data as well.
The objective function plays an important role in training. It not only provides the gradient, but also responsible for estimating a good starting point for Newton optimization. Please note that users can define custom objective functions for the task at hand. In addition to numerical features, XGBoost also supports categorical features with two different algorithms, including one-hot encoding and optimal partitioning. For more information, refer to the categorical feature tutorial. The hist and the approx tree methods support categorical features for CPU and GPU.

There’s working-in-progress support for vector leaves, which are decision tree leaves that contain multiple values. This type of tree is used to support efficient multi-class and multi-target models.

Inference

By inference, we specifically mean getting model prediction for the response variable. XGBoost supports two inference methods. The first one is the prediction on the DMatrix object (or QuantileDMatrix, which is a subclass). Using a DMatrix object allows XGBoost to cache the prediction, hence getting faster performance when running prediction on the same data with new trees. The second method is inplace_predict, which bypasses the construction of DMatrix. It’s more efficient but doesn’t support cached prediction. In addition to returning the estimated response, we also support returning the leaf index, which can be used to analyse the model and as a feature to another model.

Model IO

We have a set of methods for different model serialization methods, including complete serialization, saving to a file, and saving to a buffer. For more, refer to the Introduction to Model IO.

Model Explanation

XGBoost includes features designed to improve understanding of the model. Here’s a list:

- Global feature importance.
- SHAP value, including contribution and intervention.
- Tree dump.
- Tree visualization.
- Tree as dataframe.

For GPU support, the SHAP value uses the GPUTreeShap project in rapidsai. They all support categorical features, while vector-leaf is still in progress.

Evaluation

XGBoost has built-in support for a wide range of metrics, from basic regression to learning to rank and survival modeling. They can handle distributed training and GPU-based acceleration. Custom metrics are supported as well, please see Custom Objective and Evaluation Metric.
Distributed Training

XGBoost has built-in support for three distributed frameworks, including Dask, PySpark, and Spark (Scala). In addition, there's Flink support for the Java binding and the ray-xgboost project. Please see the respective tutorial on how to use them. By default, XGBoost uses sample-based parallelism for distributed training. The column-based split is still working in progress and needs to be supported in these high-level framework integrations. On top of distributed training, we are also working on federated learning for both sample-based and column-based splits.

Distributed training works with custom objective functions and metrics as well. XGBoost aggregates the evaluation result automatically during training.

The distributed training is enabled by a built-in implementation of a collective library. It’s based on the RABIT project and has evolved significantly since its early adoption. The collective implementation supports GPU via NCCL, and has variants for handling federated learning and federated learning on GPU.

Inference normally doesn’t require any special treatment since we are using sample-based split. However, with column-based data split, we need to initialize the communicator context as well.

Language Bindings

We have a list of bindings for various languages. Inside the XGBoost repository, there's Python, R, Java, Scala, and C. All language bindings are built on top of the C version. Some others, like Julia and Rust, have their own repository. For guideline on adding a new binding, please see Consistency for Language Bindings.

1.17.9 Git Workflow Howtos

Contents

- How to resolve conflict with master
- How to combine multiple commits into one
- What is the consequence of force push

How to resolve conflict with master

- First rebase to most recent master

```
# The first two steps can be skipped after you do it once.
git remote add upstream https://github.com/dmlc/xgboost
git fetch upstream
git rebase upstream/master
```

- The git may show some conflicts it cannot merge, say conflicted.py.
  - Manually modify the file to resolve the conflict.
  - After you resolved the conflict, mark it as resolved by

```
git add conflicted.py
```

- Then you can continue rebase by
How to combine multiple commits into one

Sometimes we want to combine multiple commits, especially when later commits are only fixes to previous ones, to create a PR with set of meaningful commits. You can do it by following steps.

- Before doing so, configure the default editor of git if you haven’t done so before.
  ```
git config core.editor the-editor-you-like
  ```
- Assume we want to merge last 3 commits, type the following commands
  ```
git rebase -i HEAD~3
  ```
- It will pop up an text editor. Set the first commit as pick, and change later ones to squash.
- After you saved the file, it will pop up another text editor to ask you modify the combined commit message.
- Push the changes to your fork, you need to force push.
  ```
git push --force
  ```

What is the consequence of force push

The previous two tips requires force push, this is because we altered the path of the commits. It is fine to force push to your own fork, as long as the commits changed are only yours.

1.17.10 XGBoost Release Policy

Versioning Policy

Starting from XGBoost 1.0.0, each XGBoost release will be versioned as [MAJOR].[FEATURE].[MAINTENANCE]

- MAJOR: We guarantee the API compatibility across releases with the same major version number. We expect to have a 1+ years development period for a new MAJOR release version.
- FEATURE: We ship new features, improvements and bug fixes through feature releases. The cycle length of a feature is decided by the size of feature roadmap. The roadmap is decided right after the previous release.
- MAINTENANCE: Maintenance version only contains bug fixes. This type of release only occurs when we found significant correctness and/or performance bugs and barrier for users to upgrade to a new version of XGBoost smoothly.
Making a Release

1. Create an issue for the release, noting the estimated date and expected features or major fixes, pin that issue.

2. Create a release branch if this is a major release. Bump release version. There’s a helper script tests/ci_build/change_version.py.

3. Commit the change, create a PR on GitHub on release branch. Port the bumped version to default branch, optionally with the postfix SNAPSHOT.

4. Create a tag on release branch, either on GitHub or locally.

5. Make a release on GitHub tag page, which might be done with previous step if the tag is created on GitHub.

6. Submit pip, CRAN, and Maven packages.

   There are helper scripts for automating the process in xgboost/dev/.
   - The pip package is maintained by Hyunsu Cho and Jiaming Yuan.
   - The CRAN package is maintained by Tong He and Jiaming Yuan.
   - The Maven package is maintained by Nan Zhu and Hyunsu Cho.

R CRAN Package

Before submitting a release, one should test the package on R-hub and win-builder first. Please note that the R-hub Windows instance doesn’t have the exact same environment as the one hosted on win-builder.

According to the CRAN policy:

   If running a package uses multiple threads/cores it must never use more than two simultaneously: the check farm is a shared resource and will typically be running many checks simultaneously.

We need to check the number of CPUs used in examples. Export _R_CHECK_EXAMPLE_TIMING_CPU_TO_ELAPSED_THRESHOLD_=2.5 before running R CMD check --as-cran [1] and make sure the machine you are using has enough CPU cores to reveal any potential policy violation.

References

1.17.11 Automated testing in XGBoost project

This document collects tips for using the Continuous Integration (CI) service of the XGBoost project.

Contents

- GitHub Actions
- Reproduce CI testing environments using Docker containers
  - Prerequisites
  - Building and Running Docker containers locally
- Update pipeline definitions for BuildKite CI
GitHub Actions

The configuration files are located under the directory `.github/workflows`.

Most of the tests listed in the configuration files run automatically for every incoming pull request and every update to branches. A few tests however require manual activation:

- **R tests with noLD option**: Run R tests using a custom-built R with compilation flag `--disable-long-double`. See [this page](#) for more details about noLD. This is a requirement for keeping XGBoost on CRAN (the R package index). To invoke this test suite for a particular pull request, simply add a review comment `/gha run r-noLD-test`. (Ordinary comment won’t work. It needs to be a review comment.)

GitHub Actions is also used to build Python wheels targeting MacOS Intel and Apple Silicon. See `.github/workflows/python_wheels.yml`. The `python_wheels` pipeline sets up environment variables prefixed `CIBW_*` to indicate the target OS and processor. The pipeline then invokes the script `build_python_wheels.sh`, which in turn calls `cibuildwheel` to build the wheel. The `cibuildwheel` is a library that sets up a suitable Python environment for each OS and processor target. Since we don’t have Apple Silicon machine in GitHub Actions, cross-compilation is needed; `cibuildwheel` takes care of the complex task of cross-compiling a Python wheel. (Note that `cibuildwheel` will call `pip wheel`. Since XGBoost has a native library component, we created a customized build backend that hooks into `pip`. The customized backend contains the glue code to compile the native library on the fly.)

Reproduce CI testing environments using Docker containers

In our CI pipelines, we use Docker containers extensively to package many software packages together. You can reproduce the same testing environment as the CI pipelines by running Docker locally.

Prerequisites

1. Install Docker: [https://docs.docker.com/engine/install/ubuntu/](https://docs.docker.com/engine/install/ubuntu/)

Building and Running Docker containers locally

For your convenience, we provide the wrapper script `tests/ci_build/ci_build.sh`. You can use it as follows:

```
tests/ci_build/ci_build.sh <CONTAINER_TYPE> --use-gpus --build-arg <BUILD_ARG> \
<COMMAND> ...
```

where:

- **<CONTAINER_TYPE>** is the identifier for the container. The wrapper script will use the container definition (Dockerfile) located at `tests/ci_build/Dockerfile.<CONTAINER_TYPE>`. For example, setting the container type to `gpu` will cause the script to load the Dockerfile `tests/ci_build/Dockerfile.gpu`.

1.17. Contribute to XGBoost
xgboost, Release 2.1.1

- Specify `--use-gpus` to run any GPU code. This flag will grant the container access to all NVIDIA GPUs in the base machine. Omit the flag if the access to GPUs is not necessary.

- `<BUILD_ARG>` is a build argument to be passed to Docker. Must be of form `VAR=VALUE`. Example: `--build-arg CUDA_VERSION_ARG=11.0`. You can pass multiple `--build-arg`.

- `<COMMAND>` is the command to run inside the Docker container. This can be more than one argument. Example: `tests/ci_build/build_via_cmake.sh -DUSE_CUDA=ON -DUSE_NCCL=ON`.

Optionally, you can set the environment variable `CI_DOCKER_EXTRA_PARAMS_INIT` to pass extra arguments to Docker. For example:

```bash
# Allocate extra space in /dev/shm to enable NCCL
export CI_DOCKER_EXTRA_PARAMS_INIT='--shm-size=4g'
# Run multi-GPU test suite
tests/ci_build/ci_build.sh gpu --use-gpus --build-arg CUDA_VERSION_ARG=11.0 \
tests/ci_build/test_python.sh mgpu
```

To pass multiple extra arguments:

```bash
export CI_DOCKER_EXTRA_PARAMS_INIT='--e VAR1=VAL1 --e VAR2=VAL2 --e VAR3=VAL3'
```

**Update pipeline definitions for BuildKite CI**

BuildKite is a SaaS (Software as a Service) platform that orchestrates cloud machines to host CI pipelines. The BuildKite platform allows us to define CI pipelines as a declarative YAML file.

The pipeline definitions are found in `tests/buildkite/`:

- `tests/buildkite/pipeline-win64.yml`: This pipeline builds and tests XGBoost for the Windows platform.

- `tests/buildkite/pipeline-mgpu.yml`: This pipeline builds and tests XGBoost with access to multiple NVIDIA GPUs.

- `tests/buildkite/pipeline.yml`: This pipeline builds and tests XGBoost with access to a single NVIDIA GPU. Most tests are located here.

**Managing Elastic CI Stack with BuildKite**

BuildKite allows us to define cloud resources in a declarative fashion. Every configuration step is now documented explicitly as code.

**Prerequisite**: You should have some knowledge of CloudFormation. CloudFormation lets us define a stack of cloud resources (EC2 machines, Lambda functions, S3 etc) using a single YAML file.

**Prerequisite**: Gain access to the XGBoost project’s AWS account (`admin@xgboost-ci.net`), and then set up a credential pair in order to provision resources on AWS. See Creating an IAM user in your AWS account.

- Option 1. Give full admin privileges to your IAM user. This is the simplest option.

- Option 2. Give limited set of permissions to your IAM user, to reduce the possibility of messing up other resources. For this, use the script `tests/buildkite/infrastructure/service-user/create_service_user.py`.  

---

508 Chapter 1. Contents
Worker Image Pipeline

Building images for worker machines used to be a chore: you’d provision an EC2 machine, SSH into it, and manually install the necessary packages. This process is not only laborious but also error-prone. You may forget to install a package or change a system configuration.

No more. Now we have an automated pipeline for building images for worker machines.

- Run tests/buildkite/infrastructure/worker-image-pipeline/create_worker_image_pipelines.py in order to provision CloudFormation stacks named buildkite-linux-amd64-gpu-worker and buildkite-windows-gpu-worker. They are pipelines that create AMIs (Amazon Machine Images) for Linux and Windows workers, respectively.

- Navigate to the CloudFormation web console to verify that the image builder pipelines have been provisioned. It may take some time.

- Once they pipelines have been fully provisioned, run the script tests/buildkite/infrastructure/worker-image-pipeline/run_pipelines.py to execute the pipelines. New AMIs will be uploaded to the EC2 service. You can locate them in the EC2 console.

- Make sure to modify tests/buildkite/infrastructure/aws-stack-creator/metadata.py to use the correct AMI IDs. (For linux-amd64-cpu and linux-arm64-cpu, use the AMIs provided by BuildKite. Consult the AWSRegion2AMI section of https://s3.amazonaws.com/buildkite-aws-stack/latest/aws-stack.yml.)

EC2 Autoscaling Groups

In EC2, you can create auto-scaling groups, where you can dynamically adjust the number of worker instances according to workload. When a pull request is submitted, the following steps take place:

1. GitHub sends a signal to the registered webhook, which connects to the BuildKite server.

2. BuildKite sends a signal to a Lambda function named Autoscaling.

3. The Lambda function sends a signal to the auto-scaling group. The group scales up and adds additional worker instances.

4. New worker instances run the test jobs. Test results are reported back to BuildKite.

5. When the test jobs complete, BuildKite sends a signal to Autoscaling, which in turn requests the auto-scaling group to scale down. Idle worker instances are shut down.

To set up the auto-scaling group, run the script tests/buildkite/infrastructure/aws-stack-creator/create_stack.py. Check the CloudFormation web console to verify successful provision of auto-scaling groups.

1.18 Release Notes

For release notes prior to the 2.1 release, please see news.
We are thrilled to announce the XGBoost 2.1 release. This note will start by summarizing some general changes and then highlighting specific package updates. As we are working on a new R interface, this release will not include the R package. We’ll update the R package as soon as it’s ready. Stay tuned!

- Networking Improvements
- NCCL is now fetched from PyPI
- Parts of the Python package now require glibc 2.28+
- Multi-output
- Federated Learning
- Ongoing work for SYCL support

  - Bug Fixes
- Maintenance
- CI
Networking Improvements

An important ongoing work for XGBoost, which we’ve been collaborating on, is to support resilience for improved scaling and federated learning on various platforms. The existing networking library in XGBoost, adopted from the RABIT project, can no longer meet the feature demand. We’ve revamped the RABIT module in this release to pave the way for future development. The choice of using an in-house version instead of an existing library is due to the active development status with frequent new feature requests like loading extra plugins for federated learning. The new implementation features:

- Both CPU and GPU communication (based on NCCL).
- A reusable tracker for both the Python package and JVM packages. With the new release, the JVM packages no longer require Python as a runtime dependency.
- Supports federated communication patterns for both CPU and GPU.
- Supports timeout. The high-level interface parameter is currently hard-coded to 30 minutes, which we plan to improve.
- Supports significantly more data types.
- Supports thread-based workers.
- Improved handling for worker errors, including better error messages when one of the peers dies during training.
- Work with IPv6. Currently, this is only supported by the dask interface.
- Built-in support for various operations like broadcast, allgatherV, allreduce, etc.

Related PRs (#9597, #9576, #9523, #9524, #9593, #9696, #9661, #10319, #10152, #10125, #10332, #10306, #10208, #10203, #10199, #9784, #9777, #9773, #9772, #9759, #9745, #9695, #9738, #9732, #9726, #9688, #9681, #9679, #9659, #9650, #9644, #9649, #9917, #9990, #10313, #10315, #10112, #9531, #10075, #9805, #10198, #10414).

The existing option of using MPI in RABIT is removed in the release. (#9525)

NCCL is now fetched from PyPI

In the previous version, XGBoost statically linked NCCL, which significantly increased the binary size and led to hitting the PyPI repository limit. With the new release, we have made a significant improvement. The new release can now dynamically load NCCL from an external source, reducing the binary size. For the PyPI package, the nvidia-nccl-cu12 package will be fetched during installation. With more downstream packages reusing NCCL, we expect the user environments to be slimmer in the future as well. (#9796, #9804, #10447)

Parts of the Python package now require glibc 2.28+

Starting from 2.1.0, XGBoost Python package will be distributed in two variants:

- manylinux_2_28: for recent Linux distros with glibc 2.28 or newer. This variant comes with all features enabled.
- manylinux2014: for old Linux distros with glibc older than 2.28. This variant does not support GPU algorithms or federated learning.

The pip package manager will automatically choose the correct variant depending on your system.

Starting from May 31, 2025, we will stop distributing the manylinux2014 variant and exclusively distribute the manylinux_2_28 variant. We made this decision so that our CI/CD pipeline won’t have depend on software components that reached end-of-life (such as CentOS 7). We strongly encourage everyone to migrate to recent Linux distros in order to use future versions of XGBoost.

Note. If you want to use GPU algorithms or federated learning on an older Linux distro, you have two alternatives:
1. Upgrade to a recent Linux distro with glibc 2.28+. OR
2. Build XGBoost from the source.

Multi-output

We continue the work on multi-target and vector leaf in this release:

- Revise the support for custom objectives with a new API, XGBoosterTrainOneIter. This new function supports strided matrices and CUDA inputs. In addition, custom objectives now return the correct shape for prediction. (#9508)
- The hinge objective now supports multi-target regression (#9850)
- Fix the gain calculation with vector leaf (#9978)
- Support graphviz plot for multi-target tree. (#10093)
- Fix multi-output with alternating strategies. (#9933)

Please note that the feature is still in progress and not suitable for production use.

Federated Learning

Progress has been made on federated learning with improved support for column-split, including the following updates:

- Column split work for both CPU and GPU. In addition, categorical data is now compatible with column split. (#9562, #9609, #9611, #9628, #9539, #9578, #9685, #9623, #9613, #9511, #9384, #9595)
- The use of UBJson to serialize split entries for column split has been implemented, aiding vector-leaf with column-based data split. (#10059, #10055, #9702)
- Documentation and small fixes. (#9610, #9552, #9614, #9867)

Ongoing work for SYCL support

XGBoost is developing a SYCL plugin for SYCL devices, starting with the hist tree method. (#10216, #9800, #10311, #9691, #10269, #10251, #10222, #10174, #10080, #10057, #10011, #10138, #10119, #10045, #9876, #9846, #9682)
XGBoost now supports launchable inference on SYCL devices, and that work on adding SYCL support for training is ongoing.

Looking ahead, we plan to complete the training in coming releases and then focus on improving test coverage for SYCL, particularly for Python tests.

Optimizations

- Implement column sampler in CUDA for GPU-based tree methods. This helps us get faster training time when column sampling is employed (#9785)
- CMake LTO and CUDA arch (#9677)
- Small optimization to external memory with a thread pool. This reduces the number of threads launched during iteration. (#9605, #10288, #10374)
Deprecation and breaking changes

Package-specific breaking changes are outlined in respective sections. Here we list general breaking changes in this release:

- The command line interface is deprecated due to the increasing complexity of the machine learning ecosystem. Building a machine learning model using a command shell is no longer feasible and could mislead newcomers. (#9485)

- Universal binary JSON is now the default format for saving models (#9947, #9958, #9954, #9955). See https://github.com/dmlc/xgboost/issues/7547 for more info.

- The XGBoosterGetModelRaw is now removed after deprecation in 1.6. (#9617)

- Drop support for loading remote files. This feature lacks any test. Users are encouraged to use dedicated libraries to fetch remote content. (#9504)

- Remove the dense libsvm parser plugin. This plugin is never tested or documented (#9799)

- XGMatrixSetDenseInfo and XGMatrixSetUIntInfo are now deprecated. Use the array interface based alternatives instead.

Features

This section lists some new features that are general to all language bindings. For package-specific changes, please visit respective sections.

- Adopt a new XGBoost logo (#10270)

- Now supports dataframe data format in native XGBoost. This improvement enhances performance and reduces memory usage when working with dataframe-based structures such as pandas, arrow, and R dataframe. (#9828, #9616, #9905)

- Change default metric for gamma regression to deviance. (#9757)

- Normalization for learning to rank is now optional with the introduction of the new lambdarank_normalization parameter. (#10094)

- Contribution prediction with QuantileDMatrix on CPU. (#10043)

- XGBoost on macos no longer bundles OpenMP runtime. Users can install the latest runtime from their dependency manager of choice. (#10440). Along with which, JVM packages on MacOS are now built with OpenMP support (#10449).

Bug fixes

- Fix training with categorical data from external memory. (#10433)

- Fix compilation with CTK-12. (#10123)

- Fix inconsistent runtime library on Windows. (#10404)

- Fix default metric configuration. (#9575)

- Fix feature names with special characters. (#9923)

- Fix global configuration for external memory training. (#10173)

- Disable column sample by node for the exact tree method. (#10083)

- Fix the FieldEntry constructor specialization syntax error (#9980)
xgboost, Release 2.1.1

- Fix pairwise objective with NDCG metric along with custom gain. (#10100)
- Fix the default value for lambda_rank_pair_method. (#10098)
- Fix UBJSON with boolean values. No existing code is affected by this fix. (#10054)
- Be more lenient on floating point errors for AUC. This prevents the AUC > 1.0 error. (#10264)
- Check support status for categorical features. This prevents gblinear from treating categorical features as numerical. (#9946)

Document

Here is a list of documentation changes not specific to any XGBoost package.

- A new coarse map for XGBoost features to assist development. (#10310)
- New language binding consistency guideline. (#9755, #9866)
- Fixes, cleanups, small updates (#9501, #9988, #10023, #10013, #10143, #9904, #10179, #9781, #10340, #9658, #10182, #9822)
- Update document for parameters (#9900)
- Brief introduction to base_score. (#9882)
- Mention data consistency for categorical features. (#9678)

Python package

Dask

Other than the changes in networking, we have some optimizations and document updates in dask:

- Filter models on workers instead of clients; this prevents an OOM error on the client machine. (#9518)
- Users are now encouraged to use from xgboost import dask instead of import xgboost.dask to avoid drawing in unnecessary dependencies for non-dask users. (#9742)
- Add seed to demos. (#10009)
- New document for using dask XGBoost with k8s. (#10271)
- Workaround potentially unaligned pointer from an empty partition. (#10418)
- Workaround a race condition in the latest dask. (#10419)
- [doc] Add typing to dask demos. (#10207)

PySpark

PySpark has several new features along with some small fixes:

- Support stage-level scheduling for training on various platforms, including yarn/k8s. (#9519, #10209, #9786, #9727)
- Support GPU-based transform methods (#9542)
- Avoid expensive repartition when appropriate. (#10408)
- Refactor the logging and the GPU code path (#10077, 9724)
• Sort workers by task ID. This helps the PySpark interface obtain deterministic results. (#10220)
• Fix PySpark with verbosity=3. (#10172)
• Fix spark estimator doc. (#10066)
• Rework transform for improved code reusing. (#9292)

**Breaking changes**

For the Python package, `eval_metric`, `early_stopping_rounds`, and `callbacks` from now removed from the fit method in the sklearn interface. They were deprecated in 1.6. Use the parameters with the same name in constructors instead. (#9986)

**Features**

Following is a list of new features in the Python package:

• Support sample weight in sklearn custom objective. (#10050)
• New supported data types, including `cudf.pandas` (#9602), `torch.Tensor` (#9971), and more scipy types (#9881).
• Support pandas 2.2 and numpy 2.0. (#10266, #9557, #10252, #10175)
• Support the latest rapids including rmm. (#10435)
• Improved data cache option in data iterator. (#10286)
• Accept numpy generators as `random_state` (#9743)
• Support returning base score as intercept in the sklearn interface. (#9486)
• Support arrow through pandas ext types. This is built on top of the new DataFrame API in XGBoost. See general features for more info. (#9612)
• Handle np integer in model slice and prediction. (#10007)
• Improved sklearn tags support. (#10230)
• The base image for building Linux binary wheels is updated to rockylinux8. (#10399)
• Improved handling for float128. (#10322)

**Fixes**

• Fix DMatrix with None input. (#10052)
• Fix native library discovery logic. (#9712, #9860)
• Fix using categorical data with the score function for the ranker. (#9753)
Document

- Clarify the effect of `enable_categorical` (#9877, #9884)
- Update the Python introduction. (#10033)
- Fixes. (#10058, #9991, #9573)

Maintenance

- Use array interface in Python prediction return. (#9855)
- Synthesize the AMES housing dataset for tests. (#9963)
- linter, formatting, etc. (#10296, #10014)
- Tests. (#9962, #10285, #9997, #9943, #9934)

JVM packages

Here is a list of JVM-specific changes. Like the PySpark package, the JVM package also gains stage-level scheduling.

Features and related documents

- Support stage-level scheduling (#9775)
- Allow JVM-Package to access inplace predict method (#9167)
- Support JDK 17 for test (#9959)
- Various dependency updates. (#10211, #10210, #10156, #10070, #9809, #9517, #10235, #10276, #9331, #10335, #10309, #10240, #10244, #10260, #9489, #9326, #10294, #10197, #10196, #10193, #10202, #10191, #10188, #9328, #9311, #9951, #10151, #9827, #9820, #10253)
- Update and fixes for document. (#9752, #10385)
- Remove rabit checkpoint. (#9599)

Bug Fixes

- Fixes memory leak in error handling. (#10307)
- Fixes group col for GPU packages (#10254)

Maintenance

- Add formatting and linting requirements to the CMake script. (#9653, #9641, #9637, #9728, #9674)
- Refactors and cleanups (#10085, #10120, #10074, #9645, #9992, #9568, #9731, #9527).
- Update nvtx. (#10227)
- Tests. (#9499, #9553, #9737)
- Throw error for 32-bit architectures (#10005)
- Helpers. (#9505, #9572, #9750, #9541, #9983, #9714)
• Fix mingw hanging on regex in context (#9729)
• Linters. (#10010, #9634)

CI

• Meta info about the Python package is uploaded for easier parsing (#10295)
• Various dependency updates (#10274, #10280, #10278, #10275, #10320, #10305, #10267, #9544, #10228, #10133, #10187, #9857, #10042, #10268, #9654, #9835)
• GitHub Action fixes (#10067, #10134, #10064)
• Improved support for Apple devices. (#10225, #9886, #9699, #9748, #9704, #9749)
• Stop Windows pipeline upon a failing pytest (#10003)
• Cancel GH Action job if a newer commit is published (#10088)
• CI images. (#9666, #10201, #9932)
• Test R package with CMake (#10087)
• Test building for the 32-bit arch (#10021)
• Test federated plugin using GitHub action. (#10336)
